NEURALGIA AND NEURITIS

Few diseases cause so much suffering as nerve pains such as sciatica trigeminal neuralgia brachialgia and intercostal neuralgia

This group of diseases is rapidly and effectively treated at Pistany (Czechoslovakia) by volcanic mud—driven to the surface by hot sulphur springs. Statistics show that of 100 patients only less than 5% do not respond to the treatment—30% are completely relieved and 65% are considerably improved

Pistany RADIO ACTIVE Mud Packs and Compresses are simply and easily applied This treatment may be successfully combined with other physiotherapeutic methods

WEST AFRICAN MEDICAL STAFF.

Vacancies at present exist for MEDICAL OFFICERS in the WEST AFRICAN MEDICAL STAFF

Qualifications Candidates must be British subjects of European parentage and under 35 years of age They must possess a double qualification and be on the British Medical Register Preference will be given to candidates who have held Hospital or Public Health appointments, or who have special knowledge of anaesthetics, radiology, surgery, medicine, ophthalmology, gynaecology and midwifery, diseases of the ear, nose, and throat, venereal diseases, etc

Salary £660 per annum, rising by annual increments of £30 per annum to £720 per annum, and then, on confirmation, £720 per annum, rising by annual increments of £40 to £960 per annum, together with a seniority allowance (payable only in West Africa) at the rate of £72 per annum After three years' service on £960, the salary may be raised to the scale of £1,000 per annum, rising by annual increments of £50 to £1,150 per annum, together with a seniority allowance at the rate of £100 per annum

Quarters Free quarters are provided or an allowance is given in lieu

Outfit Allowance An outfit allowance of £60 is granted on first appointment

Passages Free first-class passages are provided for the officer only both on first appointment and when proceeding on or returning from leave A married officer will, in certain circumstances, be granted half the cost of his wife's passages to and from West Africa

Terms of Appointment The appointments are pensionable, subject to a probationary period of three years in the first instance

Tour of Service The normal tour of service in West Africa is approximately 18 months, though vacation leave may be granted by the Governor after 12 months, and is followed by leave, with full salary, at the rate of one week for each completed month of residential service, plus the time necessarily spent in the voyages to and from England

Course of Instruction in Tropical Medicine Selected candidates will normally be required to attend a course of instruction in Tropical Medicine and Hygiene before proceeding overseas

Duties Though Medical Officers are appointed in the first instance for general service, there are good opportunities for work in special branches of medicine and surgery and for research

Further particulars and forms of application may be obtained on application in writing from the Private Secretary (Appointments) Colonial Office 2 Richmond Terrace Whitehall London S W 1.

CORYDON BUDD
Medical Superintendent

INDIAN MEDICAL SERVICE

Recruitment of European Officers.

Applications are invited from medical men for permanent commissions in H.M.'s Indian Medical Service. The terms offered include a gratuity of £1,000 on retirement after six years' service, or £2,500 after 12 years' service, together with free return passages, for those who no longer desire to remain in the Service. In other respects the terms will be as detailed below.

Candidates must be British subjects under 32 years of age at the time of application and must be registered under the Medical Acts in force in Great Britain and Northern Ireland.

CAREERS

The Indian Medical Service offers wide opportunities of medical experience including clinical preventive specialist and research work. At the beginning of his career an officer is employed on the military side which has medical charge of the Indian Army. Promotion is on a time scale up to the rank of Lieutenant-Colonel and by selection to the ranks of Colonel and Major-General. An officer may apply after one year's Indian service to have his name registered for transfer to the civil side from which appointments are made to Civil Surgeoncies which are established at the principal civil centres to provide for the medical needs of civil officials and for general medical administrative purposes; to specialist (for example public health and bacteriological) services; to research posts and to professorships at the Medical Schools.

PAY

The monthly rates of pay for European officers in the Service who have a non-Asiatic domicile are as follows:

Rank.	Service in Rank.	Basic Pay	Overseas Pay	Years of Total Service
1	2	3	4	5
		Rs.	Rs.	
Lieut.	—	500	150 150 150	1st 2nd 3rd
Capt.	(i) During first 3 years' service as Captain	650	150 £15 £15	4th th 6th
	(ii) With more than 3 and less than 6 yrs. service as Captain	750	£25 £25 £25	th 8th 9th
	(iii) With more than 6 years' service as Captain	850	£25 £25 £30	10th 11th 12th
Major	(i) During first 3 years' service as Major	900		
	(ii) With more than 3 and less than 6 years' service as Major	1100		
	(iii) With more than 6 years' service as Major	1250		
Lieut.-Col.	(i) Until completion of 23 years total service	1500	£30	13th and over
	(ii) During 24th and 25th years' service	1600		
	(iii) After completion of 25 years total service	1 00		
	(iv) When selected for increased pay	18 0		

EXTRAS.—In addition to the above rates various allowances are admissible for a large number of special appointments on both the military and the civil side which may be held by members of the Indian Medical Service. Special high rates of pay are also attached to the numerous administrative appointments open to officers in both branches of the Service.

ANTEDATES IN COMMISSION

Any service rendered by an officer during the war as a medical or combatant officer or in a position usually filled by an officer may be counted as service for increments of pay, promotion, retirement and retired pay but not for gratuity.

One half of any service in the ranks during the war may be counted as service for retirement and retired pay only.

Candidates possessing certain higher medical qualifications may be granted an antedate of one year in their commissions. Past service in certain hospital appointments may also render candidates eligible for an antedate of one year. Persons holding or about to hold resident posts at recognized hospitals may be seconded in those posts for a period not exceeding one year. The maximum period of antedate secondment or antedate and second ment combined admissible under this paragraph is limited to one year.

OUTFIT ALLOWANCE

Officers on appointment will receive an outfit allowance of £50.

PRIVATE PRACTICE

With the exception of Administrative Officers military or civil and officers holding certain special appointments officers are *not debarred from taking private practice* so long as it does not interfere with their proper duties.

LEAVE

Leave can be taken at reasonable intervals and adequate rates of leave pay are provided. Extra leave (known as study leave) which may not exceed 12 months in all during an officer's service may be granted to officers desirous of pursuing special courses of study of a post-graduate nature. During such leave study allowance at present fixed at the rate of 12s. a day in the United Kingdom £1 a day on the Continent of Europe and £1 10s. a day in the United States of America is granted to an officer in addition to ordinary rate of leave pay.

PENSIONS

The rates of pension are as follows	Per annum
	£
After 17 years' service for pension	400
„ 18 „	430
„ 19 „	460
„ 20 „	500
„ 21 „	540
„ 22 „	580
„ 23 „	620
„ 24 „	660
„ 25 „	700
„ 26 „	750
„ 27 „	800

These rates are subject to alteration on account of a rise or fall in the cost of living as compared with the year 1919 to an extent not exceeding 20 per cent. in all the revision being undertaken triennially. With effect from July 1st 1930 a reduction of 5½ per cent. has been made on this account from the amounts shown.

There are additional pensions ranging from £65 to £350 per annum for officers who have held administrative appointments.

PASSAGES.

An officer on appointment is provided with free passage to India. The wives and families of officers who are married prior to the date of the officer's embarkation on first appointment will also be provided with free passage to India subject to the payment of messing charges.

Officers and their families are also eligible for passage concessions under which they are granted a certain number of return passages home at Government expense during their service.

INSTRUCTION PRIOR TO EMBARKATION

Officers are required to undergo courses of instruction at the Royal Army Medical College and at Aldershot lasting approximately six months prior to their embarkation for India on first appointment.

Full details regarding these appointments and forms of application may be obtained from the Under-Secretary of State for India, Military Department, India Office, London, S.W.1. The Selection Committee will meet at the India Office early in January next and the selected candidates will be required to join a course of instruction commencing early in February 1931 prior to sailing for India in the Autumn of 1931. Applications should be submitted as soon as possible.

Peptalac REGD

THE NEW INSTANT PREDIGESTED FOOD

Predigestion of starch *and* milk is guaranteed and is effected under the most exact scientific conditions in our laboratories before powdering This means that when required for use it can be immediately and simply prepared by the *mere* addition of hot water The C & G Improved Roller Process is used ensuring retention of the full mineral and vitamin content with freedom from pathogenic organisms.

PEPTALAC is indicated in all those cases where the powers of the digestive tract are insufficient to deal with that amount of food necessary for maintaining health—for nursing mothers with weak digestions, in ante- and post operative surgical cases, in achlorhydria, peptic ulceration, cancer of the alimentary tract, in all forms of convalescence and in old age.

OLD AGE

Stimulates metabolism
Increases muscle tonicity
Raises respiratory exchange
Effects marked subjective improvement

"Old age being caused by degeneration of the endocrine glands, especially the thyroid and sexual glands, all that is necessary to secure rejuvenation is to improve the condition of these glands The best and easiest way to do this is to administer by the mouth extracts of these glands after their extirpation from healthy animals

"The persons treated looked considerably younger after it, to the extent of ten or fifteen years and sometimes even more The wrinkles in the face already began to disappear four or five weeks after the treatment, and, at the same time, previously corpulent persons, losing their excess of fat, were made to look slender, thus imparting a youthful impression"

(Loraud, "Life Shortening Habits and Rejuvenation," 1922)

DOSE 1 or 2 tablets three times daily.

THE GERMICIDAL ACTION OF DIMOL

INTESTINAL ANTISEPTIC

Extract from Report by independent Bacteriologist appointed by "The Lancet"
(Full Report can be read in 'The Lancet' 22nd February 1930 p 414)

1 Determination of the Rideal Walker coefficient of Dimol using organisms isolated from the faeces (*See* Table I)

2 Determination of the degree of dilution of the antiseptic leading to death of organisms in 15 mins (*See* Table II)

Test Organism	TABLE I—R W coefficient (number of times Dimol more powerful than pure phenol)	TABLE II—Degree of dilution leading to death of organisms in 15 mins
B typhosus	37	1 6500
B dysenteriae (Shiga)	34	1 6250
B dysenteriae (Flexner)	34	1 6000
Streptococcus faecalis	24	1 5500
pyogenes	27	1 6000
haemolyticus	28	1 6000
Pneumococci	32	1 7000
B faecalis alkaligenes	30	1 6000
B coli	30	1 5000

3 *Examination for toxicity* — Single dose up to 0·02 *g* (equivalent to 1/3 gr.) per kilogramme body weight was given to rabbits without producing toxic effects. Such a dose corresponds to grs. 20 for a man weighing 10 stone five times the dose advocated for therapy. No evidence of absorption as shown by carboluria was obtained. Repeated doses equivalent to two and a half times those recommended in therapy also failed to produce ill-effects when given three times over a period of four weeks.

CONCLUSIONS

1 Dimol intestinal antiseptic is found to possess a very high Rideal Walker coefficient against the commoner organisms infecting the intestine.

2 The antiseptic kills completely these organisms in 15 minutes in dilutions ranging to 1 in 7 000.

3 The preparation shows no evidence of producing toxic effects in animals even when given in very large doses. No carboluria was produced.

Copy of full Report will be sent on application to—

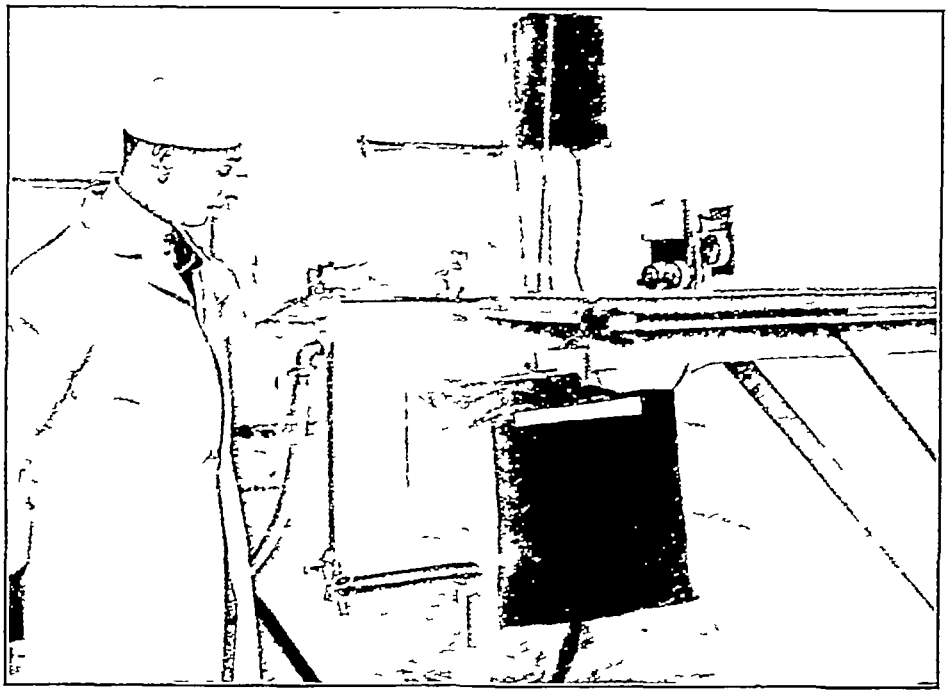
FOUR MONTHS' DIRT—

and still the vital rays come through

A folder about "Vita" Glass called "Health Through Dirty Windows" is now available and will be sent to all interested people It contains, set out graphically and in the briefest possible way, an account of experiments on "Vita" Glass carried out in a notoriously smoky industrial town in the north of England

In brief the experiments show (a) that even on a sunless February day ultra-violet rays are transmitted by dirty "Vita" Glass (b) that "Vita" Glass, coated with four months' accumulation of dirt, still transmits ultra-violet health rays, the transmitting property of the glass being practically undiminished

May we post this folder to you? Write to-day to the "Vita" Glass Marketing Board, 9, Crown Glass Works, St Helens, Lancashire



"Vita" Glass is obtainable from local Glass Merchants, Plumbers, Glaziers and Builders.

"VITA" GLASS

V337

"VITA" IS THE REGISTERED TRADE MARK OF PILKINGTON BROTHERS LIMITED, ST HELENS

MICKLEFIELD IRRADIATED MILK

TREATING THE MILK

By this Process—

(1) VITAMIN A AND NATURAL FLAVOUR ARE PRESERVED
(2) VITAMIN D CONTENT IS INCREASED 1,800 PER CENT., OR TEN TIMES THAT OF ANY OTHER IRRADIATED MILK.

One pint equivalent in Vitamin D to 600 drops or 12 grammes of average Cod-Liver Oil

A ten weeks test recently conducted at the Infants School Rickmansworth under the supervision of the Medical Officer of Health gave the following results—

(1) 18 children (controls) had their usual ordinary milk.
(2) 29 " 1/3 pint of Grade A (T T) milk five days a week.
(3) 30 " Micklefield " "

(1) Average increase in height 605 in. (2) Average increase in weight 9·72 ozs. more than (1)
(2) " " 610 in. (3) " " " 0·9 ozs. more than (1)
(3) " " " 744 in.

Full particulars appeared in an article in the LANCET January 18 1930 p 127 et seq a reprint of which will be sent post free on request

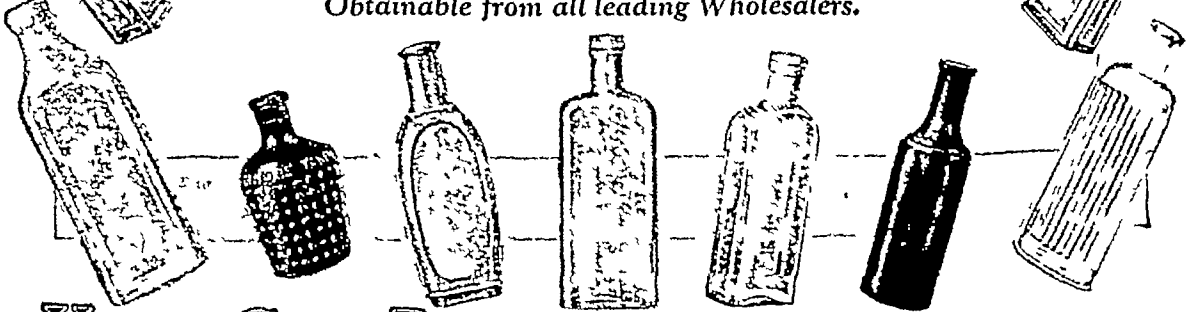
The milk is delivered every week-day in London, elsewhere by arrangement.

Write to J O HICKMAN, MICKLEFIELD GREEN RICKMANSWORTH

THE CROWNING ACHIEVEMENT

U.G.B. MEDICAL BOTTLE *Service*

DURING the past ten years at tremendous expense, a very wide range of automatic machine mould equipment has been built up by the U.G.B to cater for practically every bottle requirement of the Chemist and Dispenser. New and attractive shapes are now being added from time to time.



The Crowning Achievement was the introduction of the "Washed and Sterilised Ready-to-Use Package" which is daily growing in demand.

Only a small percentage of the actual cost of this service is passed on to the customer.

Supplied either for corks or complete with Rustless White Enamelled Screw Caps.

Once you have experienced the value and convenience of this U.G.B. Service you will use nothing else. Try it NOW and be prepared for the WINTER.

Obtainable from all leading Wholesalers.

The Collection of Overdue Accounts

WITHOUT OFFENCE

ıe Medical Profession is probably the most conservative body in the United ngdom, therefore there is no necessity to stress the value of the TWO ESTIMONIALS set out below, but they are even more remarkable than the ntents seems to imply; one is from a Member of that section of the ofession that cannot sue for their fees, and the other is from a Member actising ın one of the poorest localities ın England, and the bulk of the bts were Statute barred

— Wimpole Street, W 1
2/12/30

ır Mr Rutherford Watson

I am much obliged to you for your cheque for 30 you have sent me in respect of one special debt t you have recovered amongst others I would : to take the opportunity of expressing my great ısfaction with what you have been able to do for in this way and particularly for the admirable y in which you have done it

To judge by letters I have received accompanying ittances sent directly to me in response to your ıeals all has been done without the slightest ence and my pleasant relations with the clients ıain unaltered so far as I can judge

The work of the B M P S should be particularly ıreciated by those who like myself are subject limitations in respect of recovery by judicial cess and I shall be happy at all times to testify ordingly

Very truly yours
—— M.D F.R.C.P

Devon,
5/12/30

Dear Sir

Thanks for cheque received yesterday

I should like to say how very pleased I am with the results of your endeavours to collect my outstanding accounts

You have certainly been successful in obtaining payment of numerous accounts, to collect which all my previous efforts have been of no avail

In view of the prevailing colossal unemployment and money shortage I think the results reflect the very greatest credit on you and your obviously very capable staff

Yours faithfully,

THE BULK OF THE ACCOUNTS REFERRED TO THE ABOVE TESTIMONIAL WERE OVER SIX YEARS OLD

Your visiting card marked "B" in an envelope will produce our Prospectus

Case of Broncho-pneumonia—girl aged 10
Chart showing fall in temperature after a single injection of S U P 36

In Febrile Inflammatory Conditions

In all those infections which, starting with the common cold accompanied by high temperature, pass on with rapidity to influenza, broncho-pneumonia or pneumonia, the timely administration of S U P 36, before complications have developed, serves to abort the attack and to promote a quick and uneventful recovery

If diagnosis is not established until further infection has supervened, the administration of S U P 36 produces immediate effects which have been described as *'little short of marvellous'*—symptomatic relief is experienced, normal temperature is restored, and the duration of the disease is reduced by more than one half.

MUCOUS AND OTHER FORMS OF COLITIS

CONDITIONS of Colitis occur at all ages, and lead to much suffering, ill-health and chronic invalidism They are caused by a great variety of bacteria, which, owing to a loss of resistance on the part of the muco us membrane of the colon, maintain a chronic infection, wit hinflamma- tion of this portion of the intestinal tract

Vaccine therapy is frequently tried in this condition with disappointing results as it is pure chance if the causative organism is isolated from the host of bacteria present

The rational treatment is obviously to administer an efficient germicide which will attack and destroy *all* the bacteria present Kerol is the one substance which possesses this power, and its administration has cured many a case of mucous colitis

For intestinal disinfection, use KEROL CAPSULES (keratin-coated), they contain 3 minims of Kerol One to three capsules may be given three or four times a day after meals

Please send for Literature and Samples, which will be sent free to any member of the Medical Profession

ANDERSON DOBSON & CO., LTD
13 COOPER'S ROW LONDON E.C.3

A useful attachment for U.K. Telephone holding Memo Block sent post free on application

FOR . . . changing the intestinal flora . . . supplying bulk and lubrication

Lactose 73%, dextrin 25%—that is the proportion in which these carbohydrates are combined in this new food for changing the intestinal flora Both are more slowly absorbed than other carbohydrates, and both are able to reach the colon in sufficient quantity to cause a luxuriant growth of protective flora An acid reaction of the intestinal contents unfavourable to toxic organisms is thus produced —Lacto-Dextrin being highly efficient in promoting the growth and development of both B acidophilus and B bifidus in the colon In this pure carbohydrate food both lactose and dextrin are presented in a palatable and agreeable combination

Samples and literature of both these intestinal products will be sent to members of the Medical Profession on request to Coates & Cooper, 41, Gt Tower St London, E C 3, Sole Distributing Agents for the United Kingdom and Irish Free State.

LACTO-DEXTRIN

Manufactured by the BATTLE CREEK FOOD CO, Mich, U S

PSYLLA

an accessory for use in conjunction with Lacto-Dextrin

Where bulk and lubrication of the intestinal tract is also required, the use of BATTLE CREEK Psyllo (Plantago Psyllium) is invaluable as an accessory The small brown seed when in contact with water swells in to a soft gelatinous mass and acts most effectively both as an emollient and intestinal evacuant

A Distinct Advance Over Preparations of Acetyl-Salicylic Acid

Acetyl salicylic acid possesses a notable disadvantage Physicians have proved that it cannot be tolerated by patients suffering with a delicate stomach Consequently, the value of this medicament in the wide field in which it is indicated is very seriously reduced

"Alasil" completely overcomes this objection By combining calcium acetyl-salicylate with "Alocol," unfavourable secondary action upon the stomach is prevented This beneficial influence is undoubtedly due to the presence of Alocol" (Colloidal Hydroxide of Aluminium), which preparation has brilliantly stood the test of practice in the treatment of hyperacidity and other ill conditions of the gastric tract "Alasil" is therefore a triumph over acetyl salicylic acid It enables higher doses to be administered and maintains the patient's system under its influence for a greater length of time Analgesic, Antipyretic and Sedative, "Alasil" is indicated in all cases where acetyl salicylic acid has been used heretofore

A supply for clinical trial with full descriptive literature sent free on request

Alasil

In Sepsis and Dental Prophylaxis

In the report of the Milroy Lecture delivered before the Royal College of Physicians of London *(Lancet* April 5th 1930 p 733) attention was directed to the fundamental causes of sepsis and dental caries

It is recommended that *we should follow that more excellent way not only must growing children have a sufficient diet containing Vitamin D but that proper maternal feeding with a diet containing the same vitamin is essential while the child is yet unborn if he is to produce not only perfect deciduous but also perfect permanent teeth*

Clinical evidence proves that even after dental caries has begun the administration of Vitamin D can arrest the process of decay

The best means of providing a sufficiency of Vitamin D is through the medium of Radiostol either as a standardised solution alone or combined with Vitamin A as Radiostoleum or with Vitamins A B_1 and B_2 as

RADIO-MALT

Vitamins A B_1 B_2 and D

Builds up in underweight conditions and provides a perfectly balanced, highly nutritive diet for growing children

TO the problem of the "underweight" child Horlick's Malted Milk provides a convenient solution

For many years it has been successfully used by the medical and nursing professions for fast-growing children, for invalids, for expectant and nursing mothers — in all cases where it is particularly important to sustain strength and replenish natural energy quickly

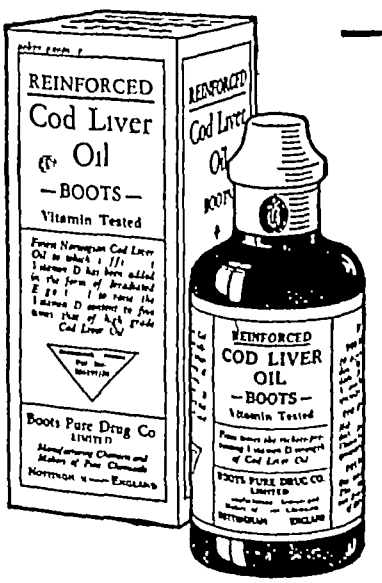
Excellent results obtained by adding Horlick's to the diet of growing children have been strikingly recorded in many thousands of letters written by parents and members of the medical profession

Made from fresh, full-cream cows' milk, selected wheat and malted barley, Horlick's Malted Milk constitutes a perfectly balanced food — containing fat, proteids, and soluble carbohydrates in correct nutritive ratio

The vitamins of its constituents are unimpaired by the Horlick process

Horlick's contains neither cane sugar nor unaltered starch, but presents in proper proportions a sufficiency of valuable malt sugars, for which children have a greater toleration Moreover, Horlick's is partially pre-digested during manufacture, thereby assuring perfect assimilation

In addition to its important body-building qualities, Horlick's has the advantage of being an extremely palatable beverage Most children like the natural flavour of malt and will drink Horlick's with pleasure And it is now obtainable also in a new Chocolate Flavoured form — identical in constituents with the original Horlick's, but with fine chocolate added



Horlick's Malted Milk (both forms) is obtainable everywhere in sealed glass bottles, at 2/-, 3/6, 8/6 and 15/- Also in tablets

Further details and supplies for tests may be obtained from Horlick's Malted Milk Co , Ltd., Slough, Bucks

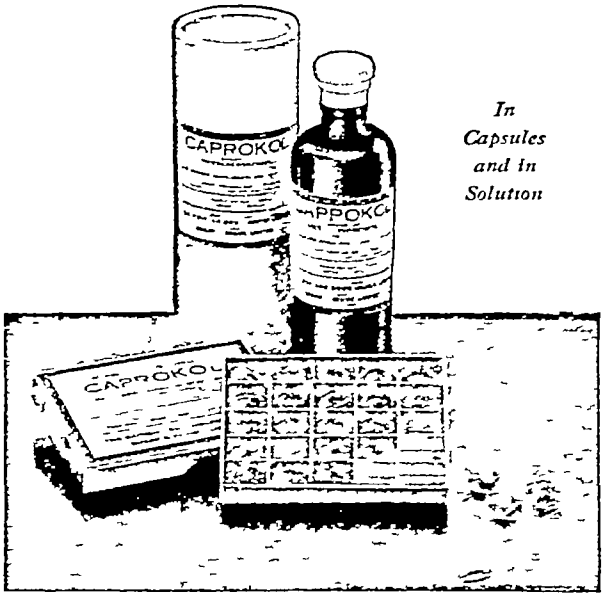
REINFORCED COD LIVER OIL —BOOTS

THE therapeutic value of Cod Liver Oil is fully appreciated by the Medical Profession It is recognised for its specific action (due to its high content of Vitamins A and D) in rickets, affections of the chest, and diseases arising out of malnutrition Boots Reinforced Cod Liver Oil is a biologically controlled preparation containing five times the amount of Vitamin D in addition to the normal amount of Vitamin A The advantage of a concentrated oil needing only a fifth of the usual dose will be particularly valuable Four fluid ounces of Reinforced Cod Liver Oil —Boots, contain the same amount of Vitamin D as one pint of the finest Norwegian oil



In 4-oz bottles, 2/6.

CAPROKOL

For Oral Administration
in the treatment of
Urinary Tract Infections

Caprokol is excreted unchanged by the kidneys it exerts a soothing analgesic effect upon the urinary mucosa and at the same time transforms the urine into a highly-germicidal solution thus Caprokol treatment not only gives prompt ease and comfort to the patient but if persisted in it ensures a continuous flow of germicidal urine over the infected field causing ultimately complete sterilisation of the urinary tract

R AND C

Specially indicated in
NEPHRITIS - URÆMIA - ECLAMPSIA - ALBUMINURIA
and allied conditions

PROMPT and proper diagnosis of kidney conditions is necessary in cases of Bright's disease and all types of renal disorders. In nine cases out of ten the administration of a specific capable of producing real results in compensating for the loss of kidney function is also necessary

For more than a quarter of a century Nephritin has been a sheet anchor to physicians in treating such disorders. Nephritin Tablets induce a marked increase in nitrogenous waste elimination. They reactivate the cells of the kidney increase urinary secretion, and induce a greater output of urea.

Given in sufficient dosage these tablets produce marked results, and restoration to normal is quickly stimulated. They are invaluable also as a prophylactic in renal complications of infectious diseases and during pregnancy The tablets are composed of the hormones of the normal kidney as they appear in nature—*absolutely unaltered.*

A Vitamin-containing food —and very much more

WHILST the presence of Vitamins in food is rightly recognised as essential, their presence is a minimum and not a maximum requirement Whilst Virol contains all the vitamins, it does not, like so many foods, found its claim to medical attention on its vitamin content alone

In Virol the relative proportions of Protein, Fat, Carbohydrate and Mineral Salts are carefully adjusted For it is recognised that the absence or deficiency of one element leads to the inefficient absorption of the other food elements present in the diet Thus—*Virol is a food complete in itself and correctly balanced*

A Food, again, must be judged by the amount and nature of the products of its digestion that ultimately reach the blood In Virol the fat is presented in the form of a highly digestible emulsion, and the proportion of protein is adjusted so as to avoid derangement of nitrogenous metabolism

The proof that Virol conforms to all the essential canons of the science of nutrition is seen by the fact that

VIROL

is used in over 3,000 Hospitals & Welfare Centres

Virol is sold in jars at 1/3 2/ 3/9 ½ gall 15/ Virol Limited Ealing London W 5

ORNAMENTATION TO ILLUSTRATE THE ISLAMIC FORM OF ARABESQUE.—Rejecting for the most part, the human form in their decorative art the Arabians fell back upon ornamental composition of a kind in which they became pioneers. Built upon a symmetrical basis it is made up of fantastic interweaving lines and combines not only fruits and flowers but geometrical forms, triangles pentagons and indeed all kinds of polygons with lozenges and festoons all of which provide inspiration for an infinite number of *Arabesques*. The Arabs combined the new and the old in such a manner as to form an originality of their own. The twelfth century wooden panel here reproduced suggests Coptic origin, but is nevertheless unmistakably Arabian.

A British Medical Association Lecture

ON

MENSTRUATION AND IRREGULAR UTERINE HAEMORRHAGE OF OVARIAN ORIGIN

BY

JAMES YOUNG, D.S.O., M.D., F.R.C.S.Ed.

GYNAECOLOGIST, ROYAL INFIRMARY; PHYSICIAN, ROYAL MATERNITY AND SIMPSON MEMORIAL HOSPITAL, EDINBURGH

It is at first sight, a somewhat remarkable fact that if we except such gross pathology as the tumours and the abnormal conditions arising from pregnancy we are still largely ignorant of the causation of the commonest gynaecological symptom—namely, irregular uterine bleeding. On the other hand it is not surprising that in the past our etiology has rested on a crude basis of pathology when we remember that our understanding of the physiological counterpart of these bleeding discharges—namely, menstruation—has itself been so incomplete. Within recent years a large amount of research has been directed to the elucidation of the physiology of the sex cycle of which menstruation forms one essential phase and in respect of some of the cardinal questions we are now in possession of a body of positive fact. It is to these new data and the bearing they are certain to have on our clinical problems, that I now wish to invite your attention.

Physiology of the Sex Cycle.

One of the most significant results of recent research is the establishment of the fact that both in its inception and in its maintenance, the sex cycle of the ovaries and the accessory organs is dependent upon the anterior part of the pituitary body. The work of Cushing and others had for many years indicated some such association by directing attention to the failure of sex development found in some pituitary disorders. After extirpation of the hypophysis the sex glands of young animals remain infantile and the secondary sexual characters fail to develop. Conversely by injecting *immature* animals with extracts of the anterior pituitary obtained from either similar or foreign species Evans[1] and others have shown that the ovaries become activated with the establishment of the sex cycle of the *adult* animal. The pituitary has no such action on the uterus and the accessory organs except through the medium of the ovary; it is impotent in castrated animals. Ovaries from immature animals transplanted into sexually mature animals become active with the exhibition of follicular activity, ovulation and the formation of corpora lutea because they come under the influence of the adult pituitary. It is thus apparent that the sex apparatus functions only when and whilst it is under this pituitary activation. The exact nature of this impulse has not been thoroughly worked out. It is unquestionably hormonal but whether there are one or two or more ingredients with different effects is uncertain. Some workers support one single influence whilst others believe that there is one hormone that controls oestrus and ovulation and another which controls the corpus luteum.

The sex cycle throughout the mammalian kingdom exhibits the same general characters. Let us first consider the lower orders. In them during the first phase of the cycle, the follicles in the ovary mature and this is correlated with an activation of the uterus, vagina and other accessory organs, which in the lower orders consists of "coming on heat" or *pro-oestrus*. This phase is succeeded by *oestrus* during which alone coitus is possible and it is at this time that the ripe follicles shed their ova either spontaneously as in the dog, the mouse, etc., or only after coitus as in the rabbit, the cat and the ferret. Oestrus is succeeded by the rapid growth of the corpus luteum from the cells of the wall of the follicle or follicles that have ovulated. This is correlated with an increase in the size of the uterus and a progressive thickening of the endometrium caused by a great growth in and activity of the glands and a vascularization of the stroma. At the end of this phase unless pregnancy intervenes, the corpus luteum degenerates and the hyperplastic mucosa of the uterus recovers its more quiescent characters in preparation for the commencement of a new cycle. There are thus three main phases in the cycle: (1) the pre-ovulational or pro-oestrus; (2) the ovulational or oestrus; and (3) the post-ovulational or luteal. In some animals—for example the horse and the sheep—such cycles succeed one another without intermission during the breeding season (the polyoestrous condition) whilst in other animals—for example the dog—there is only one such cycle during each breeding season (the monoestrous condition) followed by a prolonged period of quiescence in ovaries and accessory organs (anoestrus). When ovulation is followed by pregnancy the corpus luteum and the correlated growth in the uterus and other organs, instead of retrogressing as they do in the infertile cycle, continue in a condition of progressive development. In some animals—for example the dog, the rabbit and the ferret—after ovulation without fertilization the corpus luteum continues to grow for a considerable time and this is associated with such active changes in the uterus and mammary glands as to suggest a condition of pregnancy. To this prolonged luteal phase in a non-fertile cycle the term "pseudo-pregnancy" is given (Marshall).

In general terms the sequence of events obtaining in the cycle of the lower animals is repeated in man and monkeys, but there are some striking differences which have led to some difficulty in identification. Here the cycle is polyoestrous occupying about a lunar month, and there is no period of anoestrus. The ovarian cycle corresponds with that present in lower animals, consisting of a pre-ovulational phase of maturation succeeded by ovulation, which, in the primates, occurs any time between about the tenth and fourteenth days after the commencement of menstruation. From this stage follows the phase of luteal growth, during which the endometrium undergoes active changes involving the glands, the stroma, and the vessels. The most noteworthy distinction between the cycle of man and the primates and that of the lower animals is found in the characteristic monthly blood loss from the uterus which succeeds the stage of luteal growth, and which is associated with disintegration and shedding of a great part of the premenstrually overgrown mucosa. In man and monkeys this bleeding occurs each lunar month and lasts for from three to five days. From this time the corpus luteum undergoes rapid degenerative changes.

The Significance of Menstruation

It has commonly been believed that menstruation in man and monkeys is caused by a degeneration of the endometrium consequent upon the withdrawal of the luteal hormone and that it is therefore timed by the declension in the corpus luteum known to occur at this stage. It has been suggested that the blood loss corresponds to the extravasation into the uterine mucosa known to occur at the end of a pseudo-pregnancy in some lower animal—for example the dog (Marshall[2]). In favour of this conception there are several strong arguments. (1) It is established that for the premenstrual growth of the mucous membrane the corpus luteum is essential and therefore, its degeneration must result in arrest of this growth activation. (2) Extirpation of the corpus luteum or the ovary containing it precipitates a menstrual flow usually within forty-eight hours. This has been established by many experiments both in man and in monkeys. (3) Conversely it is known that pregnancy when menstruation is in abeyance, is associated with continued growth of the corpus luteum. (4) In some animals—and there is some evidence of a similar nature in regard to woman—abnormal persistence of an active corpus luteum leads to arrest of the sex cycle. Taken together, these facts are in harmony with the view that menstruation is the culmination of the phase beginning with ovulation and ending with the luteal stage of the development of the follicle and that therefore the timing of the event is registered by the timing of the follicular cycle.

This conception of menstruation has been finally invalidated by the observations of Corner[3] Hartman,[5] Van Herwerden[6] and others that in monkeys menstruation can occur regularly when there is no follicular cycle taking place in the ovaries—that is, when there is no

Delivered to the Lanarkshire Branch of the British Medical Association in Glasgow October 8th 1930.

ovulation and no formation of corpus luteum Moreover, in such animals there is no premenstrual growth in the endometrium Further, this type of "non-follicular" menstruation occurs in healthy monkeys living in the wild state, and it is therefore not abnormal There is evidence that a similar phenomenon can occur in women It demonstrates that the menstrual cycle is to be considered as dependent upon some cyclic changes other than those of the follicle, and which are for this purpose more basic and essential We may express it shortly by saying that there is a primary cycle with menstruation as one of its phases on which there is superimposed and accurately registered the secondary cycle of the follicle These observations are in keeping with the findings of Parkes[4] that, after ablation of the entire follicular apparatus of the mouse by means of *x* rays the oestrous cycle nevertheless continues Further, as Hartman[5] has pointed out, several observers have shown the existence of abortive cycles in the anoestrous period of animals progressing towards oestrus, but before this—that is, the period of ovulation—has been actually reached (rat, dog, ferret) Moreover, Zondek[6] has shown that after feeding mice with thallium the follicular cycle continues but the uterine cycle is arrested He attributes these results to the suspension of the oestrus-producing hormone of the ovary These considerations imply the necessity for a reorientation of our outlook both in regard to the factors underlying menstruation and the interpretation of some of the experimental data upon which the primacy of the lutcal relationship was based We have seen that experimental removal of the corpus luteum precipitates menstruation At the same time, there is evidence, both in man and in monkeys, that destruction of the maturing follicle, even before ovulation, causes uterine bleeding (Beckwith Whitehouse,[7] Hartman), so that it is not the fact of luteinization of the follicle that determines the effect of its extirpation So far, we have no means of assessing the essential significance of these experiments We may hazard the conjecture that they imply a sensitiveness of the basic rhythm to any traumatic assault inflicted on any part of the follicular or more purely reproductive apparatus of the ovary This and cognate questions are of considerable interest to us as clinicians because of their possible bearing on the common irregularity in the menstrual cycle which we find in disease

The nature of the cyclic variation in hormonal activity that determines the sequential events in the sex cycle, including menstruation, has been the topic of speculation By some a continued production of the hormone by the ovary has been predicated and the cyclic manifestations attributed to rhythmic variations in responsiveness on the part of the uterus and other accessory sex organs It has more commonly been held that the cyclic variations are determined by variations in hormonal content, which represent either alterations in the ovarian output under pituitary influences or a rise and fall in a threshold mechanism (Frank[10]) In this connexion the experiments of Pratt and Allen[11] and of Zondek[12] are suggestive The former investigators working with castrated monkeys, and the latter in an ovariectomized woman, produced menstruation by the abrupt stoppage of repeated injections of the oestrus-producing hormone of the ovary Frank moreover, has found a sharp rise in the female sex hormone in the circulating blood (as tested quantitatively by its capacity to produce oestrus in castrated mice) seven days before menstruation, and that this continues during the premenstrual phase, to stop suddenly with the onset of the flow The available data are thus in harmony with the view that menstruation is dependent upon the removal from the circulation of an oestrogenic hormone which, during the premenstrual phase, has been responsible for an activation of the uterus

Menstruation a Function of Implantation

We have seen that it is impossible to explain the bleeding phase of the cycle in man and monkeys on the basis of an analogy with the phenomenon of pseudo-pregnancy in lower animals The analogy breaks down from the unequivocal finding that, whereas the corpus luteum is essential for pseudo-pregnancy, it is not necessary for menstruation An attempt has been made by some observers to identify menstruation with the genital haemorrhage which in certain animals occurs during pro-oestrus Thus, in the dog during the phase of maturation of the ovarian follicles and even at the period of ovulation itself (oestrus), there is a bloody discharge from the mucous membrane, which may continue for as long as a week Against this conjectured analogy between menstruation and such pro-oestrous bleeding however, there is the very strong argument that in the primates ovulation typically takes place between ten and fourteen days after the onset of menstruation, and that there is therefore an interval of from six to ten days between the cessation of the bleeding and ovulation It may thus be contended that, so far from throwing light on the inner meaning of menstruation, such attempted analogies as I have mentioned serve rather to emphasize the biological uniqueness of the form this phase of the cycle assumes in man and monkeys Many years ago (1911) I[13] pointed to the fact that this phase of bleeding into and from the mucous membrane of the uterus is found in those organisms (man and monkeys) in which, at the corresponding phase of the fertile cycle, placentation is accomplished by a free extravasation of blood in the same regions I further showed that a personal study of two early human ova, the description of which I[13] have published elsewhere, and of tubal pregnancy, provided conclusive proof that the young trophoblast obtains its blood supply by provoking a wide gaping of the maternal vessels and a free extravasation of blood These conclusions, it was pointed out, were supported by the descriptions given for other early ova There was, moreover, clear evidence that these striking tissue changes are produced by a chorionic hormone which acts by eliciting a vascular and tissue response similar to that present in the pre-bleeding phase of menstruation It was contended that these observations alone satisfactorily explain (1) the peculiar structural properties of the endometrium which is adapted to respond in this specific way to the hormone, and (2) the biological significance of the bleeding phase in man and monkeys and its time relation to ovulation I have expressed the relationship between menstruation and implantation somewhat figuratively by saying that the endometrium bleeds in anticipation just as it bleeds with realization

Within recent times Hartman[5] and Corner have directed attention anew to these interesting biological questions Corner,[14] in a very clear statement of the position, says

> "My conjecture is thus that in order to provide for the highly specialized embryonic implantation of primates with its opening of the maternal blood vessels into the intervillous spaces, the endometrial process is carried so far as even to cause bleeding into the tissues during the last days of the interval, at the time during which the early embryo is to be implanted The action of the embryo alters the latter part of the process so as to inhibit or limit the haemorrhage, but if no embryo be present to utilize the extravasation, then the blood escapes into the uterine lumen and externally visible bleeding occurs Such a hypothesis seems to render the menstrual process something more than a pathological wastage, and also suggests a reason for its total absence in species which have less specialized forms of implantation"

The "hormonic machinery" by which, with embedding of the ovum, widespread bleeding into the mucosa is accomplished necessarily demands some localization of the process after the ovum's needs are complete Otherwise the hormone soaking through the tissues and reaching the distant areas of the sensitized mucosa via the blood stream must provoke extensive and disastrous bleeding. In my early work I suggested that we might see in the decidua the method by which this generalized inhibitory mechanism is expressed, and I pointed out that such a view has the advantage of accounting for the universal distribution of the decidua (reflexa serotina and vera), an explanation obviously lacking in the orthodox view that it is laid down to protect the maternal tissues against the inroads of the trophoblast This conception, which contains a germ of truth, arose at a time when the opening up of the maternal tissues was erroneously believed to be accomplished by a phagocytic action of the chorionic cells I have shown that in tubal pregnancy we sometimes discover a striking demonstration of the role thus attributed to the decidua in that the only areas of the tubal wall protected against this

hormonal dissolution are those areas which can exhibit an effective decidual response—that is the mucosa. The existence of a decidua in the uterus in such cases can be similarly explained. This conception of the antihormonal function of the decidua necessarily in view of recent work, involves a restatement of the role of the corpus luteum. The work of Loeb and others has shown that it is this body that confers upon the endometrium its deciduability and has taken in conjunction with the above considerations enables us to formulate more exactly the part which it is known to play as an essential pregnancy organ.

The Placental Hormones

Many observers have shown that hormones with properties similar on the one hand to the oestrus-producing hormone of the ovary and on the other to that of the anterior pituitary can be isolated in considerable amount from the human placenta. There is a good deal of evidence that these hormones are directly elaborated in the organ and are not, as has been suggested, merely transferred there for storage. Whilst the large scale on which they are manufactured by the placenta would seem to leave no doubt that they subserve some important pregnancy functions, the exact nature of these functions remains a mystery. I have indicated above how in the early phase of placentation there is recognizable evidence of the hormonal activity of the trophoblast. It is now well known that the secretion of the hormone similar to that of the anterior pituitary in the urine of a pregnant woman forms the basis for the very sensitive Zondek-Aschheim test for pregnancy. The urine is injected into immature mice and the activation and luteinization of the ovarian follicles constitute a positive result.

PATHOLOGICAL UTERINE HAEMORRHAGE

The impetus which the new discoveries have given to the study of sex physiology has expressed itself also in a renewed study of the pathology of the sex process. At the same time the uncertainty still surrounding the basic factors of function imposes a limit on the extent to which we can appeal to physiology for aid in our clinical problems. For this reason it is natural that whilst the development of our pathological studies has necessitated much restatement of fact in regard to the essential causative agencies we are still largely ignorant. We have seen that the physiological function of menstruation is under the hormonal regulation of (1) the anterior pituitary and (2) the ovary which by a co-ordinated mechanism operate on (3) the uterus. Not unmindful of the fact that diseased processes may, and not infrequently must, influence this tripartite mechanism from without we may profitably pass under review the ways in which each member of it may contribute to the production of irregular or excessive uterine bleeding.

The Anterior Pituitary and Irregular Uterine Haemorrhage

On this question there are few data. It is reasonably certain that dystrophia adiposo-genitalis (Fröhlich's syndrome) with its arrested sex functioning and amenorrhoea is determined by hypofunction of the anterior pituitary. On the other hand, except perhaps in the case of acromegaly where there is commonly an initial menorrhagia, we have no direct evidence of the part played by the pituitary in producing excessive bleeding. At the same time the primary part which it is now recognized to play in the control of the ovary will make it necessary for us in the future to bring it increasingly under scrutiny in all ovarian dysfunction associated with irregular bleeding. It is in the meantime legitimate to conclude that in many instances the well known influence of mental excitement or shock on menstruation may arise from a sympathetic disturbance transmuted in the pituitary into an endocrinal stimulus to the ovary. Hence for example we may imagine an explanation of the frequency with which menstruation starts prematurely in the patient faced by the ordeal of the examination room. On the basis that uterine haemorrhage of obscure origin may be controlled from the pituitary, Hofbauer[15] and others have employed *x* radiation of the region of the sella turcica.

Uterine Haemorrhage of Ovarian Origin

In a paper published in 1913 and entitled "Uterine haemorrhage of ovarian origin,"[16] I directed attention (to quote from the paper) to

> those cases where excessive menstrual and an intermenstrual loss are present and where on examination nothing abnormal or only some uterine enlargement is found. Such cases are very common. They are unceremoniously thrown into that lumber room of classification—endometritis. As a sort of hit in the dark curettage is done. On microscopic examination there is no evidence of inflammation but only an oedematous and haemorrhagic endometrium without or more commonly with an increase in the glandular elements. Many cases of glandular increase are certainly pathological. But for them glandular endometritis is a misnomer.

The views then expressed sprang from a conviction based upon an extensive study of the pelvic pathology in such bleeders. This characterized as it typically was by general uterine enlargement and endometrial thickening partook rather of the nature of an exaggeration of the functional changes occurring during the normal cycle. The paper included a study of two typical cases where in association with this pathology there were haemorrhagic lesions in the corpus luteum of the ovary. I further emphasized that

> where there is found on examination nothing abnormal except some uterine enlargement and where the mucosa is found to exhibit the appearance of so-called glandular endometritis an ovarian source should be suspected.

Subsequent experience has confirmed me in the views then expressed that except in rare instances, the terms chronic endometritis, chronic metritis and fibrosis uteri as ordinarily employed for such cases spring from a misreading of the essential pathology. A true histological picture of endometritis is rare, apart from an infected childbed or abortion, degenerating tumours in the interior of the uterus and those other conditions, such as infection after operation in which the history and pathology present more or less acute characters. Similarly a true metritis I have never seen except in the unequivocal presence of inflammation—for example in an adhesive peritonitis in which uterus and infected appendages are involved in a contact infection. The investigations of Schroeder[1] on metropathia haemorrhagica—the term which he has given to a common condition exhibiting, in association with irregular and excessive bleeding and a proliferative lesion in the uterine musculature and mucosa characteristic ovarian changes—have directed attention to ovarian disease as a frequent factor in chronic bleeding disorders. Beckwith Whitehouse[14] in this country has in a series of communications, emphasized the same lesson and has sought to explore the field of physiology for the solution of some of the problems in pathology. More recently Wilfred Shaw[19] has published the most comprehensive attack on the subject that has so far appeared, consisting as it does of a combined clinical and pathological study of 200 consecutive cases of irregular uterine bleeding at St Bartholomew's Hospital excluding instances of malignancy, polypi, caruncles, erosions of the cervix and senile vaginitis. Wilfred Shaw was able to divide the cases into different classes. (1) Of the total, 50 or about 25 per cent. fell into the category of metropathia haemorrhagica. In 50 per cent. of these there was a uniform thickening of the musculature of the uterus and typically the endometrium was thick and polypoidal and the glands were cystic and increased. The ovaries contained large unruptured or recently ruptured cystic follicles and corpora lutea were rare. Cases occurred at any age from puberty till after the menopause but the chief age incidence is 40 to 50. Frequently before the characteristic continuous haemorrhage there was a period of amenorrhoea of a duration of one month or more. 80 per cent. of the women were parous. Schroeder has explained the bleeding as being due to the absence of the inhibitory influence of a corpus luteum. (2) The second class including 72, or 36 per cent. exhibited in association with excessive loss a reduction of the menstrual cycle to two or three weeks. Examination of the ovaries showed a corresponding alteration in the cycle of ovulation. The chief age incidence again is between 40 and 50. Shaw attributes the menstrual abnormality and the uterine

pathology to hyperactivity of the ovaries (3) In a further class there were 27 cases, or 13 5 per cent, in which the essential clinical features consisted of an augmented blood loss associated with a lengthening of the cycle to thirty-five or forty-two days In some the newly acquired spacing of the cycle became more or less regular whilst with others the cycle was irregular, varying between three and six weeks There was again evidence of an underlying ovarian alteration (4) In 48 cases out of the total the etiology was obscure, and, whilst ovarian causes might be operative this could not be established (5) In only 13, or 6 5 per cent, was there histological evidence of endometritis, and in all except one the symptoms had not extended beyond two months *In none of Shaw's cases were there findings* warranting an explanation based upon such conditions as chronic metritis and fibrosis uteri, and, further, it is stated that 'there is no evidence to support the view that cases of irregular uterine haemorrhage are determined by subinvolution"

These investigations are of great importance, and, if confirmed, they will necessarily demand a complete reorientation of our outlook in regard to this question for they infer that, in the absence of a gross lesion in the uterus chronic bleeding diseases, in a ratio of over 70 per cent, are associated with ovarian disorders At the same time the exclusion of a primary uterine factor and the invocation of an ovarian dysfunction do not explain the disease complex, for we are still left with the necessity of accounting for the ovarian disturbance For this we must await the outcome of future research In this connexion I[20] have elsewhere pointed to one such possible factor in the frequency with which chronic cervicitis is associated with menstrual arhythmia and excessive loss I have found such menstrual derangements in 82 out of a consecutive series of 124 cases—that is, 66 per cent Other observers have referred to the same fact Thus Masson and Parsons[21] found that menstrual irregularity was the chief complaint in 25 per cent of their cases of chronic cervicitis, although a larger number admitted deviations when specifically questioned Jeff Miller[22] and Behney[23] also refer to this relationship In these cases there is no pelvic abnormality capable of accounting for the menstrual irregularity and excess, the examination revealing nothing more than some general uterine enlargement and some hyperplasia and proliferation of the endometrium—the conditions that is which we have seen to accompany ovarian disorders Moreover as I have shown, in a considerable number the menstrual disturbance clears up after treatment limited to the cervical condition Behney has had a similar experience, obtaining cure of menorrhagia in 63 per cent of his cases after cauterization of the cervix For these reasons I have suggested that in some way which is at present obscure, perhaps via the rich sympathetic supply of this region we may conclude that the cervical lesion leads to involvement of the ovarian function There is evidence in the lower animals of an intimate nerve relationship between the cervix and the ovary Thus in the mouse, mechanical irritation of the cervix causes the prolongation of the luteal phase normally accomplished by coitus, and in the rabbit coitus, whether fertile or infertile produces ovulation It is likely that these phenomena whilst originating in sympathetic impulses, are transformed by the pituitary into hormonal influences sent to the ovary and it is conceivable that pathological impulses from the cervix may initiate through similar channels an aberration of ovarian function I have shown that positive evidence of disease of the ovarian follicular system was found in two such cases in which the abdomen was opened for the purpose of hysterectomy

Differential Diagnosis and Treatment of Irregular Haemorrhage of Ovarian Origin

In many such cases the diagnosis can be made with approximate accuracy from a study of the clinical history combined with the absence of any gross pathology found on pelvic examination The bulk of the cases occur in women between the ages of 40 and 50 however when fibroids and cancer loom large as causes of haemorrhage, and to exclude these an exploration of the uterus is necessary Cervical cancer with its foul discharge and its indurated, friable, and frequently excavated lesion and its irregular, intermittent bleeding, is rarely a cause of difficulty In corporeal or endocervical cancer and fibroid polypoidal growths and the chronic bleeding of placental fragments, exploration alone reveals the condition The bleeding from threatened abortion may occasionally cause confusion, especially since, in such conditions as metropathia, the continued bleeding may be preceded by amenorrhoea It would seem that some post-menopausal cases of bleeding are caused by ovarian 'rejuvenescence' but, mindful of the frequency with which bleeding at this time connotes malignancy, cervical cancer should be suspected with a healthy cervix, curettage, followed by microscopical examination of the material removed, is always necessary In the last series, comprising a total of seventy-two consecutive cases of post-menopausal haemorrhage which I have had in hospital, there were sixteen cases in which no uterine pathology adequate to explain the condition was found, and in a majority of such cases ovarian factors may be postulated In three there was a condition of simple cystadenoma of the ovary

The treatment to be adopted in these conditions will be determined by various factors, of which age is the chief The fact that we are progressing towards a rational pathology justifies the hope that we are within measurable distance of a scientific therapeusis directed toward the factors that disturb the ovarian function Meanwhile, however, until we have this knowledge, the only alternative left to us in many cases consists of symptomatic treatment for the bleeding It is my practice in women over 40 to carry out an exploratory curettage to establish a diagnosis When malignancy is excluded, and as curettage is occasionally followed by cure, I discharge the patient with instructions to report if excessive bleeding return In this event she is sent to the radiologist for x-radiation of the ovaries and the production of an artificial menopause In the hospital patient this involves three visits as an out-patient Radium may be employed as an alternative This is my routine practice also in younger women where the failure of other treatment precipitates the need for drastic measures The employment of these means has, in my practice, led to the elimination of hysterectomy for such cases The operating records no longer show, as in former days, the comparatively frequent tale of "hysterectomy for intractable haemorrhage," with its not inappreciable mortality, apart from the mental and physical distress associated with all major surgery Suffering women have much reason for gratitude since the advent of radiation therapy beyond the relief it confers in the sphere of cancer treatment In young women these conditions are frequently a source of great anxiety because, on the one hand palliative measures are so commonly ineffective, and on the other hand, the above drastic therapeutic measures constitute at this age so terrible an alternative The haemorrhage of puberty and of girls in their teens which probably is practically always hormonal in origin, sometimes reacts satisfactorily to curettage general hygienic measures, the administration of calcium salts, etc In such cases and in women still in the reproductive period, we must necessarily postpone to the last moment any decision which is in its nature irrevocable, in the hope that time will bring relief The commercial ovarian preparations of proved activity, such as sistomensin, agomensin, etc, may be tried although I have not found the same response with such drugs in cases of haemorrhage as in dysmenorrhoea in which the effects may be remarkable Such therapy is in the present state of our knowledge, necessarily largely empirical, and must remain so until our knowledge increases In intractable cases x-radiation in minimum dosage may be cautiously tried in the hope that alleviation without sterilization may be accomplished On this treatment some gynaecologists have reported favourably although there is always attendant on it the spectre of overdosage, leading to permanent infertility I have had better results with radium administered in minimal dose than with x rays

In cases associated with cervicitis, in my experience the best treatment at all ages is the use of the cautery The cervix is dilated to a degree sufficient to allow ac-

the electric cautery to the internal os Three lines of incisions behind and three in front are made from internal to external os and over the catarrhal patch on the vaginal portion The cautery scars through the mucosa into the adjacent fibro-muscular wall and Nabothian follicles are individually punctured In some cases a repetition of the process at the end of a month is required After each application a plain warm water vaginal douche should be given daily for a week or ten days to act as a mechanical cleanser, and to facilitate the removal of the sloughs which sometimes form

Pathological Haemorrhage of Uterine Origin

It will have become apparent from the preceding remarks that recent advances in our knowledge have enabled us to lift bodily out of this category a large group of cases which were previously and erroneously considered as having uterine cause for the irregular bleeding and which are now to be regarded rather as ovarian aberration with secondary uterine change This applies to a large number of these cases previously described under such headings as "fibrosis uteri," "chronic metritis" 'chronic polypoidal domestritis," "chronic glandular endometritis' and "subinvolution" The discovery in cases of fibromyoma of ovarian changes similar to those found with the above conditions even raises the question as to whether the irregular bleeding found with these tumours may not in reality, sometimes spring from this cause Frank has even suggested that the tumour may derive its origin from localized overgrowth in the uterine wall arising from ovarian hyperactivity

SUMMARY

1 Menstruation can occur in the absence of ovulation and the corpus luteum and it cannot therefore be interpreted in terms of an analogy with pseudo-pregnancy in lower animals, for which a luteal phase is necessary

2 Further, its place in the cycle in relation to ovulation undermines the conjectural analogy between it and proestrous bleeding in lower animals

3 These analogies can be further invalidated and the essential meaning of its existence in man and monkeys explained by recognizing it as a function of the peculiarly haemorrhagic type of implantation of the ovum found in these higher animal forms The bleeding of menstruation and the bleeding of implantation are homologous in that they occupy the same place in the sex cycle and the external bleeding expresses the escape of the unwanted "implantation blood" in an infertile or a non-ovulating cycle

4 Many of the bleeding disorders erroneously attributed to such conditions as chronic glandular endometritis, chronic metritis fibrosis uteri etc are in reality expressions of disturbances of unknown origin in the ovarian (or combined pituitary-ovarian [2]) regulation and definite clinical entities with correlated structural changes in the ovary can be recognized

CONGENITAL DISLOCATION OF THE HIP

LATE RESULTS OF TREATMENT BY MANIPULATION *

BY

F JAMING EVANS, CBE FRCS,

SENIOR SURGEON ROYAL NATIONAL ORTHOPAEDIC HOSPITAL.

(*With Special Plate*)

For the purposes of this communication an attempt has been made to examine clinically and by x rays 70 cases of congenital dislocation of the hip which were treated by me by manipulation at the Royal National Orthopaedic Hospital between the years 1903 and 1920 I have succeeded in examining within the last two months, 25 of these cases involving 32 joints All surgeons in large cities have found a difficulty in tracing patients after a lapse of many years Stephens' reports that he could examine and x-ray 7 patients only out of 185 treated in the Hospital for Ruptured and Crippled between 1901 and 1910

The 25 cases comprised 4 right unilateral (4 joints), 14 left unilateral (14 joints) and 7 bilateral (14 joints) The average period since reduction was upwards of fifteen years and the average age of the patient at the time of reduction was upwards of 4½ years

Method Employed

During the earlier years the Lorenz method was employed with its violent stretchings its hackings" and its leverage over a wedge Gradually less violence and fewer stretchings were found sufficient for reduction and traction with the fingers replaced the wedge With few exceptions a short spica has been employed fixing one hip only in unilateral cases The first plaster has fixed the limb in the position of greatest stability and as much as 120 degrees of flexion and 110 degrees of abduction have been employed But these extreme positions have been maintained for the shortest possible period and usually within four to six weeks of reduction fixation in the position of 90 degrees flexion 70 degrees abduction and 0 degree of rotation has been possible This position has been retained until the end of the fixation period and no attempt has been made to diminish this state of 90 degrees of flexion or 70 degrees of abduction Exceptionally a long spica including the foot has maintained the limb in the position of abduction and internal rotation I have very rarely found the degree of anteversion sufficient to necessitate this position The period of fixation has varied from less than a month in a 9 months-old child to as much as one and a half years when stability was unassured A patten usually 5 to 6 inches high has allowed locomotion during the fixation period in unilateral cases After removal of the plaster the child has been encouraged to kick about and perform active exercises in the supine position for three months Standing has not been allowed until three months have elapsed from the end of the period of fixation I am afraid in some cases this rule has been broken by parents and the child has walked on its softened and decalcified neck, and that some of the changes in the neck are due to this I consider this is the most important period of treatment but in-patient treatment at this stage has been found impossible owing to pressure upon beds Massage and passive movements have rarely been employed A plaster bed holding the limb in 90 degrees flexion and 70 degrees abduction has been used at night until three years after the date of reduction For three months after walking has commenced a patten 1½ inches high has been used on the sound leg to keep up the abduction on the affected side

Clinical Results

The clinical result of these 25 cases are as follows bad 1 poor 2 good 13 perfect 9 Unfortunately there is no standard or criterion when we try to classify end results in terms of function and we are faced with many difficulties There are two constant disabilities in the unreduced hip however well it may function for locomotion —namely shortening and limp To arrive at the measure of shortening in unreduced hips I used the opportunity,

* Read before the Section of Orthopaedics at the Annual Meeting of the British Medical Association, Winnipeg 1930.

when examining over 80 cases of congenital dislocation of the hip at the Royal Surgical Aid Society during the years 1909 to 1919, of estimating the shortening in 50 consecutive cases of unilateral dislocation, which had not been subjected to any attempt at reduction, 28 were left-sided and 22 right-sided. The ages of this series ranged from 13 to 67, with a mean age of 26·7 years, and shortening ranged from 1½ inches to 5 inches, with a mean shortening of 2·55 inches. The variations of length in the 18 unilateral cases under review show a range of 1 inch shortening to 1/4 inch lengthening, with a mean shortening of 0·375 inch. The limp is an unmeasurable and variable quantity, and no single clinical examination or cinematograph record is completely trustworthy. A patient may not limp when examined or before the camera, yet with slight fatigue an asymmetry in the walk may show, from weakness in the pelvi-trochanteric muscles, however stable the hip-joint. I have therefore taken the patient's word that he or she limps, although my own observation may not have confirmed this. A short clinical examination may not have revealed a slight arthritis, is compatible with a good functional result. Of the 3 cases which gave bad or poor results, one was bilateral, reduced at the age of 8 in 1912. Subsequent experience shows that this treatment was inapplicable, and should not have been employed. Yet the patient works as a shop assistant, and is on her feet all day. X-ray examination shows anterior transposition and concentric reduction, with a flattened head and atrophied neck. Another is a right-sided condition, reduced at the age of 6 in 1914 with a concentric reduction, with active flexion of 30 degrees, abduction 30 degrees, but no rotation at all. She works as a dressmaker and swims and dances a little. The third is a bilateral case reduced at the age of 4 in 1913. She works as a milliner, can swim two lengths at the baths and cycles ten miles. She shows anterior transposition and eccentric neurthrosis. Thirteen cases (17 hips) giving good results have full, free, and painless movements. Six exhibit a slight limp when examined with a loincloth only or after exertion. They show one anterior transposition, four eccentric neurthroses and twelve concentric reductions while nine, giving perfect results, are indistinguishable from normal, except in the circumferential measurement of the upper thigh. In five there is one to two inches of atrophy in two even this difference is absent, each measuring 22 inches in circumference. X-ray examination shows two concentric reductions with coxa valga, and eight indistinguishable from normal.

X-Ray Records

Turning now to the x-ray results, I am able to show cords of all these hips, taken within the last two months. Of these 25 per cent. are accounted for by three anterior transpositions and five eccentric neurthroses, the remainder (75 per cent.) being sixteen concentric reductions and eight which are normal. In the three transpositions, two occurred in bilateral cases classed bad or poor, one occurred in a unilateral case reduced in 1906, and is a good functional result. In the five eccentric neurthroses four occurred in unilateral cases with good function, one occurred in a unilateral case with poor function. In the sixteen concentric reductions which show abnormalities, the acetabulum may show an increased obliquity or some shallowness, the femoral head may show irregularity in its sphere or flattening, the neck may show valgal or varal bending, anteversion, and stunting. I hold that some of these changes are inevitable whatever treatment is employed, and are due to the same faulty growth impulse which caused the original malformation—namely, an error of mesoblastic growth. The functional results of the cases shown with shallow acetabula and increased obliquity are so good and the joints so stable that I think that roof formation by an osteoplastic graft is only called for in extreme cases of shallowness and obliquity. Whether the changes in the head and neck are due to an absence of growth impulse to trauma from reduction, thus allying it to Kummell's disease to osteochondritis, to osteo-arthritis juvenalis, or to several of these causes still remains an open question. Obviously trauma should be avoided and compression prevented during the decalcified stage, the former by reduction at an early age, and the latter by after-care. Froelich,[2] Judet[3] and Bade[4] agree that a functional result is consistent with such changes in both constituents of the joint. Bade has observed good functional results with eccentric acetabular formation. The normal deep acetabulum and long femoral neck give 130 degrees are provided for athletic, gymnastic, and battle feats, walking, running, dancing, and swimming can be carried out with shallower acetabula and shorter necks provided the joint is stable and enjoys free and painless motion. The eight joints that are classed as normal are indistinguishable from the hip-joint on the sound side.

Conclusion

My view is that manipulative reduction at the early age should be employed. In children under 2 or 2½ reduction can usually be obtained with the greatest ease whilst gently stretching the adductors. In older children if an early reduction is not obtained two further attempts at intervals of seven to ten days should be made, after reduction without force will usually be possible. After three unsuccessful attempts, capsulotomy is indicated in order to deal with the obstruction of soft parts. If, after successful reduction, redislocation occurs from failure of growth of the superior and posterior borders of the acetabulum the border should be levered over the head and held by a bone graft. The age limit for manipulative reduction is 7 to 8 in unilateral, and 5 to 6 in bilateral cases. In cases beyond these age limits open reduction is indicated.

PLEURAL EFFUSIONS IN GENERAL PRACTICE *

BY

W. ARNOLF DICKSON, M.D., M.R.C.P.Ed., F.R.C.S.Ed., D.P.H.,

TUBERCULOSIS OFFICER, GLOUCESTERSHIRE; CLINICAL MEDICAL OFFICER, GLOUCESTERSHIRE COUNTY COUNCIL

(With Special Plate.)

I HAVE chosen this subject for two main reasons. Firstly, it has been impressed on me that in the examination of cases of chest disease the possibility of effusion is not sufficiently kept in mind and so it is often missed; secondly, there is even yet a lack of clear teaching as to what should be done when an effusion has been found.

Let me illustrate these assertions by examples taken from two of the great teaching hospitals of London. At an inquest held on a man who had died under an anæsthetic in a London hospital while being operated on for gallstones, the coroner summed up as follows:

"There was a large amount of fluid in the chest, but it was not discovered. It ought to have been, but it was not. This man has died under an anæsthetic administered for the purpose of an operation for a disease from which he was not suffering. It is a case of mistaken diagnosis."

With regard to treatment, I heard Sir Thomas Horder open a discussion on this subject at Manchester, in which he mentioned that he very seldom saw a pleural effusion in hospital, as his house-physician had aspirated before he had had an opportunity of examining the patient. These selected graduates are apparently under the delusion that the correct treatment for a pleural effusion is to aspirate as completely as possible immediately it is diagnosed. "If they do these things in a green tree, what shall be done in the dry?"

Classification of Effusion

As is well known, effusion may be a sequel to injury of the chest wall, and the nature and subsequent course of such an effusion, which practically always contains blood, is determined by the character and severity of the injury. These cases are really surgical, and will be excluded from consideration. We need only study two varieties (*a*) clear, (*b*) thick.

* Substance of a presidential address to the Gloucestershire Branch of the British Medical Association, November 13th, 1930.

Clear Effusions

he clear effusion is the commonest one with which I l There is a simple oedema of the pleural sac, irring most frequently in heart disease, which may for purpose be dismissed in a word It is a transudation lear fluid of low specific gravity, non-inflammatory in ure, and is associated with oedema elsewhere It is part of a general interference with the circulation of ue fluids, and its importance in the pleural cavity is ely mechanical It should be removed when it is sing distress, and as often as is necessary, for it ws little tendency to absorption, the cause as a rule ng continuous and progressive

wish especially to direct attention to the clear effusion en coming on insidiously and without evident cause— so-called *primary* or *idiopathic effusion* This is an idate, with a higher specific gravity and a firmer clot n the transudate of heart disease (Should doubt exist any particular instance the pathologist will soon settle question if 5 c.cm are submitted to him) It is result of an inflammatory process and the process ich causes it is tuberculous An effusion of this type uld never be regarded, as it often is as an illness in elf, to be considered cured when the fluid has apparently appeared it is proof of an underlying lesion demanding g and serious treatment The many demonstrations om both the pathological and clinical standpoints that is effusion is essentially tuberculous, are still unheeded numbers of practitioners, indeed, there is no lack of tive opponents of the idea

The *Lancet* report of the Manchester discussion on this bject, to which I have already referred contains the llowing passage Dr Russell objected strongly to the eat interference with working life and the mental agony flicted by a tuberculous outlook in these cases Treatment by ordinary means was quite satisfactory" There e of course, numerous instances of tuberculous manifestations subsiding under treatment by ordinary means, en in the absence of a correct diagnosis but who is be the infallible prophet who will say in any particular se that the obvious warning which effusion gives may fely be ignored, and that the patient's agony of mind f that is a reasonable term) is not simply being deferred ll it is too late to be alleviated? The pathologists e now coming down very decisively in favour of ie 'tuberculous outlook" in every one of these cases linicians with large experience are more convinced even an the statistics suggest Without presuming to rank rself among the clinicians with an exceptional store of perience, I may say that in the county of Gloucester have seen enough, in the past seventeen years to enable ie to speak with conviction if not with authority Scores times have I seen patients who gave a history of an ttack of pleurisy with effusion for which they were kept ff work for only a very limited number of weeks and hen I examined them I found active pulmonary tuberculosis with tubercle bacilli in the sputum, and a prognosis arying from 'moderate" to 'extremely bad" In the undred beds at Standish House for adult pulmonary cases here were last month twenty-seven patients whose illness ad been associated with effusion A number of these atients had undoubtedly missed, owing to neglected ffusions, the most favourable opportunity for treatment nd some tragic after-histories might have been avoided ad this sign of tuberculosis received due consideration at he proper time In my opinion a diagnosis of idiopathic leural effusion is in fact a diagnosis of pulmonary tuberculosis, in the Ministry of Health classification and the ractitioner ought to recognize it as such and notify accordingly

What of the effusions which are not diagnosed It must not be imagined that these are few and far between Every year I see large numbers of them The chief pitfall n diagnosis, when the patient is really examined, is the old and erroneous belief, which still unaccountably persists that breath sounds are invariably absent over an effusion All that can be said about breath sounds in this condition (and it is not particularly useful) is that they may be absent, or weak, or altered The stethoscope in fact is frequently more misleading than helpful There are no physical signs pathognomonic of fluid they may all be found in other conditions It is quite a common mistake for a doctor to think he cannot be dealing with an effusion because he hears loud bronchial breathing over the dull area If in addition he discovers whispering pectoriloquy, he then feels confident that there is *consolidated* lung plus a cavity Yet exquisitely pure whispering pectoriloquy may be heard over an effusion, and bronchial breathing is about as commonly present as absent The golden rule is when in any doubt put in a needle This is a procedure which ought to be practically painless if it is properly done The common faults are (*a*) the use of a blunt needle, (*b*) the use of a defective syringe (*c*) absence of local anaesthesia especially of the pleura (*d*) want of care in determining a rib interspace, (*e*) the use of too short or too fine a needle It is truly surprising to see how often a rib is fouled in putting a small needle into the pleura A frequent source of failure is to locate an interspace with the point of a finger, and then go about an inch wide horizontally, forgetting the angle at which the ribs run, and inevitably hitting bone

The ideal procedure is somewhat as follows

The skin is well painted with tincture of iodine or colloidal iodine over the dull area usually just below the angle of the scapula or in the fifth or sixth space in the axillary line A fine needle is fitted to the syringe which is filled with sterile 2 per cent novocain solution Two fingers are used to define the intercostal space and between them a bleb is produced by intradermal injection of novocain A larger needle is then fitted to the syringe and pushed vertically and slowly through the bleb and the insensitive intercostal muscles the patient being asked to say whenever any sensation is felt this indicates proximity to the pleura The remainder of the novocain is then used to infiltrate the pleura the cavity is entered the piston is withdrawn and the syringe fills with fluid The needle should be sufficiently long to avoid driving it up to the hilt as that is where needles tend to break a troublesome complication If the syringe draws blank then either the dullness is not due to fluid or there is pus too thick for the needle In the latter case a really stout needle should be passed along the anaesthetized tract (this will be painless) and if pus is present it should be found

Treatment

Let us suppose first that a clear exudate has been withdrawn into the syringe What is to follow in the way of treatment The patient should be kept in bed until all constitutional symptoms have passed and the morning and evening temperature has been normal for at least a week A properly kept chart is of the greatest importance This will mean on an average rest in bed for three or four weeks The fluid itself, if at all possible should be left severely alone The only legitimate indication for simple aspiration is distress due to the bulk of fluid which is as in the case of the transudate a purely mechanical consideration Here however we have not a failing heart to contend with All other indications all warnings as to remote consequences, should be disregarded It is surprising how little distress a really large effusion sometimes produces Fluid right up to the clavicle may not inconvenience the patient to any extent and moreover may spontaneously disappear in three or four weeks Interference frequently does harm imagine what happens inside a chest when a large effusion is rapidly withdrawn by a Potain's aspirator the bottle being kept as near a vacuum as enthusiastic pumping can make it the fluid discharging with an obscuring froth full bore into the container We have all participated in such a scene Meanwhile a high negative pressure is being induced inside the pleural cavity followed by a rapid expansion of diseased lung and a quick change from the lymphatic tasks of collapse to the flooding of the lung tissue with fluid Apart from the risk of pain syncope and even of sudden death the risk of dissemination of disease of the lung is far from negligible I will not complicate matter by describing the replacement of fluid by air a valuable procedure as this is very rarely done in general practice Should simple aspiration be resorted to it is best not to withdraw more than about a pint at a time and the actual withdrawal should occupy ten minutes Some people advocate injecting a little of the exudate into the patient's own tissues a species of auto-serotherapy Considerable benefit has been claimed for it but I should not recommend it as the essential precautions are difficult of fulfilment

The point in treatment which I wish to emphasize above all else is the recognition that primary clear pleural effusion is tuberculous, and that to allow a patient to resume his ordinary work in a few weeks, as is often done, is a dereliction of duty on the part of the practitioner. There is presented to us in this condition an opportunity of treating early pulmonary tuberculosis, and for the usual type of patient sanatorium treatment offers the only hope of carrying out the necessary disciplined life for the requisite length of time. Objection will almost certainly be raised to this course, and unless the position is rationally explained to the patient his co-operation can hardly be expected. If a patient cannot or will not enter a sanatorium, then a careful routine should be laid down for him for a period of three to six months after his effusion. His normal activities should not be resumed within the period.

Thick Effusions

Pathological curiosities such as chylous fluids will not be considered. Only two varieties of thick effusion need be mentioned: (*a*) the haemorrhagic, and (*b*) the purulent.

The Haemorrhagic Effusion

The haemorrhagic effusion does not require much comment. It is said to point to the presence of new growth, but blood is not infrequent in tuberculous effusion. The diagnosis cannot be made from the effusion alone, it must be established by further investigation, which is beyond the scope of this paper. The point to remember is that blood in an effusion has no real diagnostic significance.

The Purulent Effusion

When pus is found, the diagnosis in one important sense is finally settled. It cannot be too often insisted on that if there is any reason to suspect pus in the pleural cavity, the sole method of diagnosis worth speaking about is the use—and, if necessary, the repeated use—of the exploring needle. All clinical criteria, all other methods of diagnosis, including *x* rays, however useful they may be are in comparison merely guesswork. As a rule, when a practitioner finds pus in a chest the first person he thinks of is the surgeon. He is quite wrong. It ought to be the pathologist. The immediate and overriding requirement is to establish the identity of the organism responsible for the pus, as everything in treatment depends upon this. A list of pyogenic organisms which may be found can be seen in any textbook. The list is long, exhaustive, and confusing. Amid this welter of possibilities the general practitioner has to think only of three which are of essential significance—namely, the pneumococcus, the streptococcus, and the tubercle bacillus. The first two are found in acute conditions, often with life actually in the balance, when a wrong move may turn the scale. Clarity of mind and of knowledge is here of the first importance. Should a pathologist not be available (and there must be few cases where he is not) then the differentiation between these two has to be made on clinical grounds.

Taking first the pneumococcal group, if, in a case of lobar pneumonia the crisis has occurred but the pulse rate continues high, suspicion should immediately be aroused as to the development of an empyema. The physical signs may suggest that the pneumonia has not resolved, but in the presence of a high pulse rate after the crisis the exploring needle should be used as a matter of routine. When pus is found it is of a thick, creamy consistence.

Very different are the conditions in a streptococcal broncho-pneumonia. Here there is commonly an exudate in the first week of the pneumonic process. This exudate is abundant, and is free in the pleural cavity, there are no adhesions. The exploring needle withdraws thin, cloudy pus not in the least like the "laudable pus" of a pneumococcal case. The two types require treatment which is radically different, although immediate operation is sometimes the only treatment considered. Osler wrote in his textbook: "It is sad to think of the number of lives which are sacrificed annually by the failure to recognize that empyema should be treated as an ordinary abscess by free incision." Doubtless this lament was justified at the time it was written, applying, as it presumably did, to pneumococcal cases. But, unfortunately, the advice to treat empyema as an ordinary abscess by free incision has been applied indiscriminately to all types of cases. Pus in the chest is obviously quite different from an ordinary abscess. Immediate operation, when pus was found, was the rule in the American training camps during the war. In one camp, out of eighty consecutive cases, the mortality was 84 per cent.; the average mortality was 48 per cent.—this in young men. These were streptococcal cases. Owing to the work of the American Empyema Commission, which assumed responsibility for treatment in three camps, the mortality rate fell to 4 per cent. And the essential change they introduced was staying the hand of the surgeon. As they themselves point out, the chief danger to be feared in streptococcal cases is premature and meddlesome surgery. The modern point of view was admirably stated by Dr. Edwards, opening a discussion at the Medical Society of London two years ago. He said: "It should be recognized at the outset that the treatment of empyema should never be regarded as an emergency requiring immediate operative intervention." To paraphrase Osler's phrase, it is sad to think of the number of lives which are sacrificed annually because this lesson is not fully appreciated. The critical question in connexion with operation is, Has the pneumonia subsided? Till this can be answered in the affirmative, open operation should be deferred. The pneumococcal empyema, with its creamy yellow pus formed about four weeks after the onset of the illness, should be handed over to the surgeon at once for adequate drainage, which usually means resection of a rib under a local anaesthetic. The streptococcal cases must on no account be operated on at once, or the chances of recovery are immediately reduced. The pus must be aspirated as required to reduce pressure, over a period of about three weeks until it becomes frankly purulent and adhesions have formed. By that time the pneumonia has subsided, and the case is ready for the surgeon.

A few months ago I was asked to see a schoolboy of 15 where the anomalous physical signs had raised the suspicion of acute tuberculosis. The boy was gravely ill with a streptococcal pneumonia, and repeated aspiration was carried out till the fourth week, when a rib was resected and all went well. Had this been done whenever pus was found, I have no hesitation in saying that the boy would have died. Sometimes the pus is absorbed completely, by accident or design it is not removed. Last year I saw a case which I am convinced belonged to this small group. The patient was a boy, aged 6, whose father had died from tuberculosis. He had been examined several times, and looked thin and white, but nothing had been found except a few small cervical glands, which were of no special moment. In May, 1929, this boy was stricken with an acute illness diagnosed as broncho-pneumonia and was removed to a local hospital. For three days his temperature was over 104° F. It then came down somewhat, but there was no sign of the pulmonary condition clearing up, and on the thirteenth day of the illness an *x*-ray film was taken which showed an almost uniform opacity over the left lung (Plate, Fig. 1.) I heard of all this from the boy's doctor about a month after the illness began. He kindly sent me notes of the clinical condition, and also the *x*-ray film. His notes read: "Temperature now swinging to 101° at night, normal in the morning, night sweats, dull up to spine of scapula on left side, bronchial breathing with some crepitations over same area." He added that in view of the family history and physical signs, he was sure the condition was tuberculous. I replied that the film did not suggest acute tuberculosis of the lung and advised putting in a needle. I saw the boy some days afterwards. In the interval a second *x* ray film had been taken which opened a "fluid level" in his left chest. When I saw him his evening temperature was 103°. He looked very white and ill. There was still dullness on the left side, from the base to the spine of the scapula, with patches of loud bronchial breathing and numerous coarse crepitations in the upper third of the left lung. I was told that the chest had been explored three times with a negative result. Being naturally loath to add anything, however trivial, to the distress of a child already somewhat exhausted by the examination, but, it must be confessed, rather against my better judgement, I accepted the risk excluding the possibility of pus, and, as the only reason

rmative, committed myself to a diagnosis of acute rcle, with a hopeless prognosis In spite of this the d persisted in slowly recovering and a month ago the x ray film showed that everything had cleared up pt for some thickened pleura in the middle of the left (Plate, Fig 2) The patient is looking well, and re are no physical signs in the che t

ases of missed empyema are I believe, not so rare as might expect As in the case just related the long-wn-out nature of the illness, the loss of weight, the lor, and profuse sweating may lead to an erroneous gnosis of tubercle I see them occasionally

ecently I examined a boy of 12 who had been ill nr weeks with these symptoms There was dullness l bronchial breathing over most of one lung I put a needle and found pus, which was up to the second

This boy was operated on next day, and did very well

was once asked to see a young man said to be dying of er ulosis as it was thought a second opinion might be a fort to the relatives I was told of the long illness the ting the drenching night sweats and the physical signs ich put the diagnosis beyond all doubt He was not expected live for more than twenty four hours When I visited him I s surprised to see him lying so quietly a distressing dy pnoea d been described to me as a marked symptom I then learned it during the previous night the shortness of breath had become reme leading to partial unconsciousness and such violent ruggling that it took three men to hold the patient in bed the throes of this struggle suddenly there was a report audible all in the room the patient's chest had burst and pints of pus re ejected as from a hose with immediate relief Certainly saw the wall plastered by pus 4 feet from the floor at a distance 6 feet from the bed There was a circular opening about the ze of a shilling in the third right interspace in front leading to ie pleural cavity The subsequent operation was entirely successful

The remaining group of cases, that involving the tubercle icillus, is not one with which as a rule, the general actitioner has much to do, unless he has a patient for hom some optimistic surgeon has resected a rib As ie sinus will discharge for the rest of the patient's life, e will see quite plenty of it

Conclusions

1 Do not be misled by physical signs
2 In cases of *any* doubt use the exploring needle
3 Remember that primary clear effusion is tuberculous
4 When pus is found, open operation should not be ountenanced till the lung process has subsided This neans, in pneumococcal cases, after the crisis, in streptococcal cases, three weeks or more from the onset of the llness and in tuberculous cases, never

TREATMENT OF LYMPHATIC GLANDS IN CARCINOMA OF THE CERVIX UTERI *

BY

MALCOLM DONALDSON MB, FRCS

PHYSICIAN ACCOUCHEUR WITH CHARGE OF OUT PATIENTS ST BARTHOLOMEW'S HOSPITAL

In the majority of cases of malignant disease the problem of the surgeon is how to treat metastases and it is well to consider why these distant growths should be so much more difficult to deal with than the original tumour

The destruction of the original tumour by means of excision or cautery dates back thousands of years all the advance made on the surgical side has been concerned with a better treatment of metastases When it was realized that carcinoma tended to spread by lymphatic drainage operations were devised to remove all the lymphatic glands and vessels which drained that area This increased the severity of the operation very considerably and the high primary mortality in many cases such as Wertheim's operation was due to the greater shock, the risk of haemorrhage, and the increased possibility of sepsis in such a large area of disturbed tissue

When radiotherapy first came into use, and it was found possible to heal the primary growth it appeared likely that the lymphatic areas would be dealt with far more satisfactorily by excision Unfortunately this has not so far proved to be the case, and the reason is by no means clear

The most likely cause appeared to be insufficient irradiation In many cases the gland are situated further from the surface, and they are therefore undoubtedly more difficult to irradiate with adequate intensity, but it is equally true that in other cases—for example, the lymphatics of the neck—the glands are, comparatively speaking superficial, and no such difficulty exists Accumulating experience would seem to indicate that the metastases are more radio-resistant than the primary growth

In a bacterial infection we know that the glands do much in preventing the spread of the disease The organisms have to pass through a cordon of glands before getting to the rest of the body and, as a rule the glands deal with the invaders very successfully The idea that the glands act in the same way in malignant disease is at first sight a tempting one but is it not possible that the glands in the case of neoplasm act in the very opposite manner—namely, by forming a centre in which the malignant cells can grow more readily? If the malignant cells which wander from the original tumour had the same opportunity of growth as in the glands, should we not find large masses in the tissues all the way along to the glands If microscopic sections are taken of the area between the original tumour and the lymphatic gland, the lymphatic vessels will very often be found to be completely blocked by cells but it is not until the glands are reached that large masses of cancer are found It seems obvious therefore that the cells which are wayland on their journey from the tumour do not have the same power of division and growth as those at a distance—namely in the lymphatic glands This can only mean that either the body has a resistance to the neoplastic cells in the intervening space or that there are factors in the glands which actually encourage growth The latter hypothesis is suggested at least by the fact that a tonsillar extract has a definite growth promoting substance for tissue culture and that tonsillar growths are very radio-resistant

So far we have considered only the question of cell growth There is however another aspect of the case that must be considered—whether the cells in these special positions are more radio-resistant Here we are faced with the problem whether the action of radiotherapy is a direct or an indirect one If we think of radio-action as being purely direct then it is only possible to think of the individual cell as being more resistant There is however, a growing suspicion that the disappearance of growth in the body is not mainly direct action but to a very large extent indirect action through the changes brought about in the surrounding cells. If this is true, then it may well be that the changes in the glandular tissue are far less than those in the other tissues of the body and therefore the action on the malignant cell is less intense

It is not difficult to suggest experiments that might help to throw light on this subject—for instance the direct implantation of tumours into glands before and after irradiation It has of course been shown by Murphy and others that implanted tumours do not take so well in an area that has been previously irradiated but I know of no experiments in which a comparison has been made between the effects of inoculating an irradiated gland and of inoculating a gland with an irradiated tumour the dose of irradiation being the same in both cases The mere fact that a previously irradiated area prevents an inoculated tumour from taking may prove to be of great significance in early cases of malignant disease It will perhaps be found that by a prophylactic irradiation of the glands cells will be unable to settle down and grow as effectively as they otherwise might

It is perhaps presumptuous for a mere clinician to try to discuss these biological problems of radio-sensitivity The most we can do is to try out various techniques by which the infected lymphatic areas can be better irradiated and experiment with various doses

One of the earliest types of malignant disease to be successfully treated by irradiation was carcinoma of the cervix uteri In early days the treatment was somewhat crude but in spite of this fact good results were obtained locally At the present time there are several different

* Read in opening a discussion in the Section of Obstetrics and Gynaecology at the Annual Meeting of the British Medical Association Winnipeg 1930.

techniques used in the vaginal application, and it can be said that any one of these will get rid of the growth in the cervix and vagina

It is possible that in some of the techniques the area irradiated is rather more extensive than others, but in no case can sufficient irradiation be applied per vaginam efficiently to deal with the glands far back in the pelvis—for example, near the bifurcation of the iliac artery. Of recent years the problem of glandular metastases in cases of carcinoma of the cervix has been approached by means of *x*-ray therapy. This combined method is extensively used in the Radium Institute in Paris and in many other centres. We at St. Bartholomew's are doing two series of such cases, one by means of radium plus *x* rays, and the other by means of vaginal application of radium and intra-abdominal radium.

It was in 1919 at the Brussels Radium Institute that the first attempts at intra-abdominal radium were made briefly the technique used was as follows. After placing the patient in the Trendelenburg position, the abdomen was opened and examination made of the pelvis. Next, an incision was made at the base of each broad ligament, and a tube of radium, containing 10 mg. of radium element *screened with the equivalent of 1 mm. of platinum* plus rubber, was placed in each broad ligament. In addition, three or more needles were placed through the lower end of the uterus. The ligatures from these containers were brought out through the abdominal wall at the lower end of the incision, the whole pelvis was then packed with six to eight yards of gauze, and the end of this gauze left hanging from the wound, together with the sutures. The abdomen was then closed, except for the place occupied by the sutures and tag of gauze. After a lapse of four or five days the gauze was pulled out, likewise the containers.

During 1923–24 the author used a modification of this technique in thirteen cases. In his experience it seemed to give rise to a rather severe peritoneal reaction, and for a time it was abandoned. An examination of the figures, however, revealed the fact that seven of the thirteen had lived for a period of five years or more, although two of these have recently died. It was therefore decided once more to try intra-abdominal irradiation, but to modify the technique. This has now been done as follows. At least six weeks are allowed to elapse after the vaginal treatment, so as to allow the cervix and vagina to heal before irradiating the pelvis. The abdomen is then opened with the patient in the Trendelenburg position, and a careful examination made, not only of the pelvis, but of the aortic glands and liver, if these are involved it is obviously useless to proceed further. If the pelvic glands alone are involved, or even if there seems to be no glandular involvement, twenty radium needles are placed right round the pelvis. Each of these needles contains 2 milligrams distributed over an active length of 32 millimetres, the walls of the needles are 0·5 mm. of platinum. The uterus is held well forward, and, starting at one sacro-iliac synchondrosis, the parietal peritoneum is picked up with forceps and the needle inserted as far as the eye just under the peritoneum. The next needle is placed about one centimetre from the first, until the outer border of the uterus is reached. This generally involves the use of five or six needles, sometimes an extra needle is placed deeper in Douglas's pouch, so as to irradiate the utero-sacral fold and the tissues lying below it. The same operation is carried out on the opposite side of the pelvis. Each needle is provided with a strong silk suture and a coloured glass bead, which is passed along the suture close to the eye of the needle. The glass bead serves two purposes: first, it prevents the suture from cutting through the thin peritoneum, secondly, it is very useful in finding the needles when removing them later. When the needles are in position all the sutures on one side of the pelvis are tied together, and their ends pushed down into the pouch of Douglas. The uterus is then allowed to fall back into the pelvis, and three or four needles are placed in front of the broad ligament (again subperitoneal, except for the eye and the bead), in order to irradiate the obturator glands. These sutures are likewise tied together, and allowed to fall down in front of the uterus. The abdomen is then completely closed for seven days. At the end of that time it is again opened to remove the needles, and then closed.

Dodd of the Westminster Hospital avoids the second laparotomy by putting the sutures through the abdominal wall, each suture being covered by a tube. In addition, I understand, he generally removes any palpable gland.

Other techniques of irradiating the glands have been suggested, for instance, Professor Daels of Ghent described a method by which an extraperitoneal channel was made reaching from the anterior superior iliac spine to the ischio-rectal fossa on the same side. A tube of radium attached to a chain was then drawn along this channel.

Results of Intra-abdominal Irradiation

The immediate results of the intra-abdominal irradiation as practised by the author are really very satisfactory. At first sight the idea of opening the abdomen twice within a week is rather startling, but it is surprising how little shock the patient experiences, as a rule the wound heals by first intention. Obviously it is an operation which cannot be performed on very feeble elderly patients, or when on opening the abdomen, the pelvis is found to be full of adhesions.

The results from point of survival rate are as follows:

Patients Treated with Intra-abdominal Irradiation

Degree	Name	First Treated	Died Period Survived		Living	
			Years	Months	Years	Months
2	A. D.	12/12/25		10		
2	K. H.	25/10/23	5	7		
4	A. A.	16/1/24			6	6
2	B. M.	23/1/24			6	6
3	A. H.	12/2/24		9

3	F. W.	2/2/24		11		
4	C. McC.	10/4/24	1	10		
3	H. N.	23/4/24			6	3
3	M. B.	3/7/24			6	—
3	G. B.	—/9/24	6	—		
1	N. S.	5/3/25			5	4
3	M. M.	11/3/27	1	4		
1	M. I.	5/8/26			3	11
		New Method				
4	M. H.	2/6/27	1	1		
2	M. B.	20/9/27			2	11
1	E. C.	22/3/28			2	4
3	K. L.	26/1/28			2	6
4	A. D.	11/2/28	1	—		
4	A. G.	8/3/28		2		
4	B. B.	19/4/28			2	3
1	E. N.	—/4/28		10		
2	F. D.	21/5/28	1	9		
2	A. G.	3/5/28			2	2
1	F. H.	8/6/28			2	1
4	F. O.	28/7/28			2	—
3	B. H.	10/9/28	1	—		
1	M. W.	29/9/28			2	4
3	F. W.	8/11/28			1	8
1	E. B.	3/1/29			1	6
4	M. P.	14/2/29	1	1		
2	B. P.	6/12/28			1	7
4	S. J.	28/2/29			1	5
4	K. C.	30/4/29			1	3
2	A. T.	6/6/29			1	1
1	F. W.	22/10/28			1	9
2	M. P.	29/11/29				8
3	F. A.	17/11/29				6

It is evident from the above table that sufficient time is not elapsed and that the number of cases is insufficient to justify any conclusions whether this method of irradiating the glands will increase the five-year survival rate, but the immediate results are satisfactory enough to encourage the author to persevere with this method

APPENDIX CONCRETIONS OPAQUE TO X RAYS

BY

C ALEX WELLS MB ChB FRCS

ASSISTANT SURGEON ROYAL SOUTHERN HOSPITAL LIVERPOOL.

(With Special Plate)

A CONDITION to which very little attention has been directed in standard literature is that of appendicular concretions opaque to x rays and large concretions in the appendix in general Several points of very real interest to the surgeon are involved and the case described here is sufficiently graphic to attract attention first as to the possible errors in pre-operative diagnosis arising from this cause secondly as to the embarrassment which may arise at operation more particularly in an acute case if we are not alive to the possibility of the occurrence of a really large appendicular concretion and lastly the troublesome sequelae which may be occasioned

Case Report

In April 1929 a man aged 39 was admitted to the Royal Southern Hospital in a condition typical of acute appendicitis with abscess formation He stated that up to within a week of admission he had been perfectly well when he had begun to feel pain in his right iliac fossa which had however not prevented his working until twenty four hours before his coming in when it became very severe and he vomited several times An appendix abscess was obvious and this was drained with the escape of a concretion The following day there came from the wound a calculus the nature of which was not immediately recognized the possibility of renal or biliary origin being entertained This stone was analysed and reported to contain calcium and magnesium phosphate a slight trace of iron a small amount of fibrin and no bile pigments or salts The pathologist remarked that it was of a very hard nature As the wound failed to clean up in the usual time lipiodol was injected up the sinus and a stereoscopic radiogram made which demonstrated a track leading to a large round shadow rather mottled in character This was interpreted as a calcified gland acting as a foreign body in an abscess cavity and exploration was decided upon After a tedious dissection a stone was disclosed lying in the lumen of the appendix which was quite clearly traced in its entire length The lumen at the centre was distended into a large bulbous swelling surrounding the calculus which was removed from a cavity completely lined with mucous membrane The appendix was then removed its outer coats being densely adherent but healing was rapid and uneventful

Description of the Calculus

In size shape and surface the calculus very closely resembled a walnut It was a deep red brown colour and extremely hard On being cut across the outermost shell only was found to be of this extremely hard consistency Just within this layer was a second lamina of mineral salts slightly less hard and the centre of the stone was occupied by a very much softer structureless mass The hospital laboratory reported that the nucleus was composed of an amorphous debris most probably faecal in origin The middle layer contained carbonate and phosphate of calcium and magnesium the carbonate appearing to predominate The outermost layer of all was composed almost wholly of triple phosphate with some calcium carbonate and earthy phosphate Other writers have reported a similar composition[1] and formation[3]

Origin of the Calculi

From this description it would seem clear that the stones in this instance were derived from local faecal accretions in the appendix This method of origin appears to be the common one although foreign bodies[4] have been described forming the nucleus and the question has been raised[2] as to the possibility of gallstones finding their way to this position Only one case is described in the article quoted and this contained very many small faceted calculi about 2 mm in diameter containing calcium phosphate and organic matter but no cholesterol bile salts or pigments The writer quotes Howard Kelly[4] and Mewdam Eccles as subscribing to the belief that the majority of these bodies are faecaliths formed *in situ* and not gallstones In one interesting case[5] the calculus was formed chiefly of bismuth which was traced to a bismuth meal taken by the patient for x ray purposes two years previously This stone measured 4½ by 1½ cm O T Williams was struck by the observation that appendix concretions are commonly larger than the normal appendix lumen and infers from this that they probably grow *in situ* as the result of salts being deposited on their periphery by the mucous membrane the fact of the excretion of inorganic salts by the intestinal mucosa being recognized He found support for this suggestion in the disproportionately large amount of calcium present in appendix concretions compared with enteroliths in general He further found an increased quantity of fats and suggested that the calcium occurred as a soap Maver and Wells[3] agree that as compared with enteroliths concretions found in the appendix contain an excess of fats and of calcium and support the suggestion that the fats are derived from the mucous membrane of the appendix itself but they do not agree that the bulk of the calcium occurs as a soap

DISCUSSION

In the journals of the last twenty years references to this condition are sufficiently plentiful to make it abundantly clear that its interest is far from being purely academic and is in fact of a highly practical nature

Diagnosis General Characteristics — The x ray appearance will in most cases be that of an irregularly calcified mass—that is mottled In the example quoted the centre was faecal and the salts were deposited in the periphery but the shadow was not particularly annular in form and reference to the cases in the literature confirms the suggestion that this characteristic is not usually present Although calcined chiefly in their outermost portions appendicular calculi do not throw a ring shadow Such a shadow has however been described with multiple nuclei Gottschlich and Fittig[14] describe lamination In this case the shadow is roughly circular in outline and this appears to be the common form Fusiform shadows are not described as a rule Multiple shadows may occur they are neither the rule nor the exception When present facets are found between opposed surfaces[1] The largest number of calculi removed is reported as four of which the biggest measured 2 by 1.5 by 1 cm[11] Demonstrable movement of the shadow will depend upon the degree of inflammatory fixation and must surely be limited as a rule In practically all circumstances the respiratory excursion will be negligible The size of the shadow is surprising In the case described it measured 3.25 by 2.25 cm and other instances have been recorded where the stones measured 2 by 1½ cm[1] 4½ by 1½ cm.,[8] and 1 2½ by 3 cm[12] One observer reports his case as "unique in the annals of surgery" The appendix contained two tapering concretions measuring respectively 1.5 by 6 cm and 4 by 1 cm[11] The pre-operative recognition of these stones seems to have been peculiarly rare Writing in 1915 Pfahler and Stamm[1] state that they were able to trace only one case which had been correctly diagnosed before operation this one having been discovered by Weisflog in 1906 when two stones were found in the appendix in the course of a radiological examination for ureteric calculi Case, at Detroit, in 1916 reported two cases correctly diagnosed by x rays In many of the cases reported there was an abscess formed in relation to the appendix and a concretion lying free in the cavity[1 13] J B Murphy[13] indicates the danger of all concretions in

the appendix causing sudden perforation without premonitory symptoms and producing an immediate acute peritonitis

Differential Diagnosis from Urinary Stones—The general characteristics just outlined should be sufficient to distinguish in most instances between an appendicular calculus on the one hand and a renal or ureteric calculus on the other. A shadow thought to be in the kidney should move on respiration and be shown in quite different positions in two photographs taken at the height of inspiration and of expiration; whilst if doubt should still exist a pyelogram should be sufficient to clear it up. A shadow thought to be a stone in the ureter should again present very little difficulty in the majority of cases. Such stones are almost constantly fusiform in shape, except when of very small size, and again, except when very small throw a uniform or a uniformly laminated dense shadow. An opaque bougie passed up the ureter will demonstrate the relationship of the shadow to that structure. It is perhaps permissible at this point to urge the use of a stereoscopic *x* ray if recourse be had to opaque catheterization. The one dimensional picture is of use if the two shadows lie well apart, but may be misleading if they should be superimposed. Douglas and Lewald[1] in their paper say that in one of their cases the stone, after removal, had an *x* ray density equivalent to that of a ureteric calculus, whilst instructive errors of diagnosis are reported among others by Hunner,[4] Seelig,[16] and Eastmond.[17] The last two writers each describe independently a case of ureteric obstruction caused by an adherent appendix containing a concretion resembling a ureteric calculus. In one of these cases an opaque catheter was passed and the error was confirmed by its being arrested at the point of adherence. It is quite rightly emphasized that a single *x* ray in such a case gives insufficient information. Radiograms must be made either stereoscopically or by lateral photography. Another writer[18] describes a similar instance of careful investigation leading to a faulty conclusion. He draws attention to the frequent mistake of removing the appendix for a pain of renal or ureteric origin, and describes an instance of the reverse error. Two fairly uniform shadows well illustrated in the article, were observed in the line of the ureter, an opaque bougie was passed, and, whilst the stones were not actually touching it, they were seen to lie at only a short distance from it and to move when the bougie was moved. Opaque fluid was then injected into the ureter, which was found to be dilated and this larger shadow overlay the stone shadows. The diagnosis of ureteric calculi was considered complete and operation embarked upon resulting in the discovery of the appendix lying on the posterior parietal peritoneum adherent to the ureter and containing two stones. In commenting on this particular instance of mistake in diagnosis there would appear to be two points which might be criticized. First the excretory function of the kidney does not seem to have been compared with that of its fellow, and secondly it seems probable that a stereoscopic *x* ray following injection of the ureter would have obviated the mistake which, however, it must be conceded, was a very natural one in the circumstances.

Differential Diagnosis from Gall-stones—This problem does not appear to have arisen very frequently no doubt because it presupposes an abnormal situation for either the gall-bladder or the appendix. One most instructive case may be quoted.[19] Two large concretions were seen throwing good shadows below and to the right of the tip of the twelfth rib. The case was primarily believed to be one of gall stones and was finally operated upon as such, but not before a full urological investigation had been undertaken. An *x* ray showed an opaque catheter lying with its tip in contact with the shadows and the urologists were satisfied that these were of kidney origin. It is worthy of note, again that the photographs were not stereoscopic. However the bulk of opinion was in favour of gall-stones and a laparotomy was performed. The appendix was removed having been found fixed high up behind the colon and containing in its tip the two stones.

The position of stones in the biliary apparatus is far from constant, so that this error is one apt to recur but at the present day it should be avoidable with the aid of cholecystography. Further, whilst most gall stones give no shadow, such shadows as are thrown are more usually annular. None the less it is true that a group formed of a large number of very small opaque gall stones does throw a mottled shadow, which is not characteristic of gall stones in general.

Differential Diagnosis from Mesenteric Glands—Curiously enough, this does not seem to have been very seriously entertained by the majority of writers consulted. In my own case one thought the most probable explanation of the shadow was that the appendix abscess had led to the exposure of a mass of calcified mesenteric glands and these were acting as a foreign body preventing the cessation of the discharge. It is possible that had a bismuth meal been given one might have been able to demonstrate that the stone was lying in the appendix but it seems more likely that such an attempt would have failed. Considering the question broadly, it would appear that the differential diagnosis must depend upon (*a*) the characteristics of the shadow, (*b*) its degree of motility and (*c*) its possible relation to a bismuth meal following preliminary measures if indicated, to exclude urinary and biliary origin. Ordinarily, of course the large opaque concretions commonly found in the appendix cause a filling defect in the appendix shadow. Kleeblatt[20] suggests an inflation of the colon in doubtful cases, and Hurter[21] a barium enema.

SUMMARY

A case is described of a large stone in the appendix opaque to *x* rays.

The origin and surgical significance of such bodies is discussed.

The diagnosis is discussed and the differential diagnosis from urinary stones, gall-stones, and calcified glands is considered in some detail.

Such cases as could be traced in the literature and which bear on the subject are described.

For his help and permission to publish this account I am much indebted to Mr John T Morrison, in whose absence this case came under my care.

A CASE OF HUMAN INTESTINAL MYIASIS

BY

J. F. D. SHREWSBURY, M.B., CH.B., D.P.H.,

LECTURER IN BACTERIOLOGY, UNIVERSITY OF BIRMINGHAM

(*With Special Plate*)

Reports of cases of myiasis—infestation with fly larvae—are infrequent in the medical literature of this country. Possibly the incidence of infestation is higher than the published reports suggest, especially in regard to intestinal myiasis, since in those cases in which larvae are only present in small numbers the condition may pass unrecognized.

The case here reported is that of a little girl aged 3 years, a doctor's daughter. The child suddenly developed a mild enteritis, which began with an attack of vomiting and persisted for about a fortnight. During this period her father noticed on two separate occasions a single larva in her motions. Eventually, some three weeks after the onset of her illness, two more larvae were found in the chamber one morning immediately after the child had urinated. No faeces were passed on this occasion, but, in view of the previous findings, the larvae were most probably passed per anum. There were never any symptoms of the urethral or vaginal irritation that would certainly have accompanied the presence of fly larvae in the urethra or the vagina. No more larvae were evacuated, and the child made a speedy and complete recovery from her enteritis.

The larvae were originally sent to Dr. P. C. Cloake, honorary assistant physician to the Queen's Hospital, Birmingham, who brought them to me. I, in turn, sent one larva to Major E. E. Austen, keeper of entomology, British Museum (Natural History), who identified it as the larva of the dipterous fly, *Anisopus fenestralis* and generously gave me permission to incorporate his report, which follows:

Anisopus (*Rhyphus*) *fenestralis* Scopoli.

This insect breeds normally in fermenting organic matter such as cow dung, the effluent from farmyard manure heaps, sap exuding from wounds in trees, water in tree holes, and the decaying roots of certain plants. In one instance the species was found breeding in a human liver which had been exposed to the air after having been preserved in 10 per cent. formalin for seven years; the larvae have also occasionally been found in cider and home-made wine, and in one instance they caused damage to the comb in a beehive. As its name implies, the adult insect, which although quite incapable of biting somewhat resembles a mosquito in appearance, is often to be found on the windows of living rooms.

The two larvae I received from Dr. Cloake were unequal in size, the larger one being about half as big again as its companion. The larger larva measured exactly 1 cm. in length by 0·5 mm. in breadth. The larvae were, however, identical in structure and colouring.

I am indebted to the courtesy of Mr. F. W. Edwards, Major Austen's colleague, for the following expert description by which the larva of *Anisopus fenestralis* may be recognized:

Complete absence of legs, but distinct brown head present. Body consisting of three thoracic segments and ten abdominal. The thoracic segments show conspicuous reddish brown markings on the sides, and less conspicuous bands are present on the abdominal segments. The first eight abdominal segments each consist of a narrower portion at the base divided by a suture from a larger posterior portion. The respiratory system has two pairs of opening, one on the first thoracic segment and the other at the extreme tip of the body, the latter is surrounded by five small pubescent lobes. The last two abdominal segments are small. The anus is surrounded by a plate on the eighth segment.

In human intestinal myiasis infestation can occur apparently by one of two routes, either the ova of the offending fly are ingested and pass through the stomach unharmed, the larvae hatching out in the intestines, or the fly actually oviposits on or near the anus of an individual at stool. The ova hatch rapidly in this situation, and the larvae make their way through the anus and travel upwards into the large bowel. This path of infestation is probably not uncommon in districts where the old earth closets are still in use (Hewitt, 1912), since many of the dipterous flies that provoke myiasis are attracted to sewage and the females oviposit on faecal matter. In the case reported, however, infestation most probably resulted from ingestion of the ova. Little children frequently suck their fingers, and are also fond of rubbing their fingers up and down window panes. As Major Austen has pointed out, *Anisopus* is commonly found on the windows of living rooms, and oviposition is certain to occur occasionally on window frames when the fertilized female is unable to escape from the room to find suitable faecal or vegetable material.

Human intestinal myiasis in this country, judging from the published cases, is not apparently of grave import as a general rule. Enteritis, of a more or less serious degree, invariably accompanies the passage of the larvae through the intestinal tract, but the symptoms clear up rapidly after the larvae have been evacuated. The larvae do not appear to attack the intestinal mucosa, subsisting on the food material available in the faeces. When the larvae are present in large numbers, however, the symptoms are proportionately more severe, and the patient may be seriously ill. In the adult, the passage of fly larvae per anum is at least an unpleasant, and frequently a terrifying experience, and in the published cases the psychological effect upon the adult patients is usually evident. There is, moreover, always the risk that the larvae may be carrying intestinal pathogenic bacteria, or may pave the way for an infection with such organisms.

Treatment does not seem to exert much effect upon the larvae, which leave of their own accord per anum, when approaching maturity. The usual vermifuges are of little value, but intestinal disinfectants, mild purgatives, and high enemata may hasten their departure in certain cases.

I wish to thank Drs. W. P. Blore and P. C. Cloake for their permission to publish the clinical material, and to express my grateful appreciation of the generosity of Major Austen and Mr. Edwards in allowing me to utilize their reports.

'FAT NECROSIS" OF THE BREAST

BY

H. A. COOKSON, M.B., F.R.C.S.ED.,

PATHOLOGIST, ROYAL INFIRMARY, SUNDERLAND

(*With Special Plate*)

Drs. LEE AND ADAIR[1] were, I believe, the first to describe this condition in a report to the American Surgical Association in 1920, when they described two cases. The same authors reported three further cases in 1922, making five in all. A sixth case was recorded by Mr. Geoffrey Keynes[2] in the *British Journal of Surgery* 1924–25, and a seventh case was the subject of a contribution by Professor Hadfield[4] in the *British Journal of Surgery*, 1925–26. Professor Hadfield refers to Mr. Rowntree[3] as having described a case of this nature in the *Lancet* in 1925. The condition therefore appears sufficiently uncommon to be an excuse for describing another case of the condition.

Case Report

A woman aged 56 was admitted to the Royal Infirmary, Sunderland, complaining of a tumour lump in the left breast. Eighteen months before admission she had fallen and injured the breast, and six months after her accident she had noticed a lump. This lump had recently slightly increased in size, and there was slight pain. On examination it was seen that the breasts were large and pendulous, and that there was a small nodule at the periphery in the lower and medial quadrant of the left breast. The skin was of normal appearance over the tumour, but was adherent to it. There was free movement on underlying structures, and no glands were felt in the axilla. The lump was tender on pressure, but felt firm. It was softer in the middle than at its edges. Mr. Hamilton Ross, the surgeon in charge of the case, excised the nodule by an elliptical incision and using a diathermy knife, after which the specimen was sent to the pathological department for examination.

Pathological Report

Macroscopical Examination—The tissue was almost entirely fatty but there were one or two nodules showing a chalky white appearance

Microscopical examination showed that the nodules were made up of large cells with a peculiar foaming cytoplasm there were also large giant cells of foreign body type The condition showed fat phagocytosis The breast tissue in the vicinity showed a fibroblastic reaction The histological appearances were similar to those described by Mr Keynes and Professor Hadfield, but were perhaps earlier in development than Mr Keynes's case and later than Professor Hadfield's case Although fibrosis was not advanced it had already commenced and the boundaries of the fat globules could be traced only with difficulty

Photomicrographs of the condition are shown on the special plate to which reference should be made There is demonstrated abnormal fibrosis due perhaps, to the trauma, and the beginning of the necrotic lesion is seen The close relation to the skin shows why the lesion appears fixed to the skin, and so simulates malignancy

The practical point in fat necrosis (so called) even of the breast appears to be that this interesting condition may be mistaken for early carcinoma of the breast The small size of the lesion however, its superficial situation and the absence of axillary glands are points against such a diagnosis Usually there is a definite history of accident the breasts are typically pendulous, and naked-eye examination shows the characteristic chalky white appearance of the nodules Histologically the picture is fairly characteristic, and I feel we are indebted to the writers referred to in this paper for placing this peculiar condition on a firm clinical and pathological basis

I venture to suggest that instead of "fat necrosis" the condition should be called 'mammary panniculitis'

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

SPASMODIC STRICTURE OF THE OESOPHAGUS

A PATIENT of mine a fisherman aged 66 complained of marked loss of weight indigestion for many years and constant vomiting of all food with large quantities of mucus for eight or nine months Latterly this had become worse so that he could not even keep down fluids His food stuck at a point which seemed to correspond with the cardiac end of his stomach On examination nothing abnormal could be felt in his abdomen but he was remarkably thin and emaciated

A bismuth meal revealed a peculiar large sausage shaped shadow lying almost horizontally across the lower chest Little or no bismuth passed beyond this shadow, and there was no irregularity at its lower end to suggest the presence of ulceration (malignant or otherwise) At first sight this shadow looked like a dilated stomach with its pylorus turned round to the left I passed a Hurst's oesophageal bougie, however, and resisted, when it was

clearly seen that the shadow was an enormously dilated and markedly curved oesophagus Attempts to dilate the stricture with bougies did no good and the patient's condition became worse It was therefore decided to open the stomach and my colleague Dr Keene did this At the cardiac orifice he found no thickening or sign of malignancy but there was very marked kinking and on attempting to dilate the orifice manually a certain amount of resistance was noticed Unfortunately the operation did not relieve the condition and the man died three days later

At post-mortem examination the enormously dilated oesophagus was found but no hypertrophy of the cardiac sphincter Obstruction was however still complete, even water would not pass through into the stomach Apparently the primary condition was one of cardiac spasm or achalasia and later complete obstruction supervened owing to the sagging of the dilated oesophagus and kinking of the lumen at the cardiac orifice

CRETINISM AND MONGOLISM IN THE SAME FAMILY

I HAVE been unable to find any record of cretinism and mongolism occurring in the same family and the following example may therefore be worth recording

The mother is a healthy and fairly intelligent woman aged 40 who has been married twice The first child of the first marriage born when she was 27 is a mongol, now aged 13 Eight months later she was delivered of a dead foetus 'the head was very large and had to be punctured before birth By her second marriage she had first a normal child and then a cretin now 6½ years old The latter first came under my care at the age of 1½ sent by Dr Taylor medical officer of health for Berks She was then a typical cretin unable to sit up with a large mouth snub nose coarse sparse hair and a sallow complexion suffering from slight blepharitis and from constipation There was a slight diffuse swelling over the isthmus of the thyroid There was very marked improvement with thyroid, but the child has never become

quite normal partly owing to the fact that the family lives in a remote part of the county and there have been occasional lapses in thyroid administration

The photograph of the mother with the two children was taken recently

CLINICAL AND SCIENTIFIC PROCEEDINGS

BORDER COUNTIES BRANCH: ENGLISH DIVISION

ANTE NATAL CARE

AT a meeting of the English Division of the Border Counties Branch held at Cockermouth on November 7th, Mr H. HARVEY EVERS, M.S., F.R.C.S., delivered a British Medical Association Lecture on ante-natal care. The number of members and non members present surpassed all records.

Mr Harvey Evers said that the subject of his lecture must make a strong appeal to an audience composed largely of general practitioners practising obstetrics in the Border Counties. Ante-natal care was a branch of obstetrics which had been his special interest for a number of years, and all graduates of the Newcastle School were proud to be able to associate with it the name of Rutherford Morison, their Emeritus Professor of Surgery, who was one of the first to urge the necessity for scrupulous care of the expectant mother. Reference was then made to a new comprehensive maternity scheme just launched in Cumberland. Mr Evers was delighted to hear that doctors throughout the county were giving this scheme such whole hearted support, since it was, to his mind, the first serious effort made in this country to secure the co-operation of the general practitioner in the obstetrical sphere of preventive medicine. He thought that the secret of success of the perfect maternal service (in its wide sense) was continuity of care and supervision before during and after labour. Dr F. H. Morison's suggestions constituted a serious attempt to secure this for every woman in Cumberland who wished to have it. Ante-natal care was not a separate specialized part of midwifery it should be an ordinary part of the routine of a general practitioner. The specialist need only be available to decide major points in diagnosis and treatment. Moreover too much must not be claimed for, or expected of, ante-natal care: it must be regarded as an adjunct to and not a substitute for good midwifery. The regime must be rigid if the best results were to be attained. The generally accepted claims on behalf of ante-natal care were stated as follows: (1) it could make pregnancy more tolerable by removing or alleviating the 'minor horrors'; (2) it could make pregnancy safer by alleviating the results of existing diseases or disabilities such as heart disease enormously by reducing the incidence of eclampsia and diminishing the dangers of haemorrhage and its results; and (3) it could make labour easier and safer by reducing the dangers of contracted pelvis or disproportion, correcting most of the malpresentations, and decreasing the risk of sepsis.

Ante-natal Care in General Practice

The outstanding features of routine ante natal care in general practice were given as follows: (1) the patient was encouraged to book not later than the third month. At this interview dates were noted, complaints were elicited and dealt with, outstanding features of the medical history were investigated, the previous obstetrical history was carefully analysed, general advice about hygiene was given, and a general examination of the patient was carried out where found to be necessary. This latter should include a urine examination and a blood pressure reading if possible. Finally, the patient was instructed about the prompt reporting of certain important abnormalities, such as obstinate constipation, severe vomiting, haemorrhage of any kind and however slight, discharge, eye symptoms, and oedema. (2) The urine was tested once a month up to four months, once a fortnight till the end of the eighth month, and once a week during the final month. (3) A further abdominal examination was made during the fifth month, this being a good time also to check dates, to obtain a further blood pressure reading, and to hear the foetal heart. *The external pelvic measurements might be* estimated at this examination. (4) A most important abdominal examination followed at the thirty-sixth week to determine, and if necessary correct, the lie of the foetus, and to ascertain whether or not there was any disproportion between the foetal head and maternal pelvis. Examination of the feet and legs, and of the urine and blood pressure were also undertaken as a routine, as at all other examinations. This regime constituted the indispensable minimum of ante-natal supervision, and in the vast majority of cases was all that was required. Obviously however abnormalities cropping up during the course of pregnancy occasionally called for much more frequent consultations and examinations. In the opinion of the speaker, routine vaginal examination was unnecessary, and should only be resorted to under the following definite indications: reason (from external examination) to suspect contracted pelvis; haemorrhage at any time during pregnancy, and however slight, purulent discharge; very occasionally cases of doubtful presentation, such as a doubtful breech in a primipara, acute or persistent pelvic pain, and retention of urine occasionally. In many thousands of cases, Mr Evers estimated his vaginal examinations at between 7 and 10 per cent.

Special Indications in Pregnancy

He then proceeded to discuss some of the "minor *horrors" of pregnancy—such as pains in the abdomen*, sides, and back, etc.—and indicated their pathology and treatment. The great importance of an adequate and properly fitting abdominal support was strongly emphasized, and types of belts were demonstrated. The value of calcium therapy in many of the painful conditions was indicated. The troubles due to constipation, flatulence and infection of the urinary tract were enumerated, and their management fully discussed. The value of intensive alkaline treatment, saline purgation, and scrupulous dieting in cases of *B. coli* infections was pointed out. Reference was next made to the significance and correct interpretation of albuminuria, and the importance of scrupulously regular urine tests was emphasized. Even a trace of albumin must arrest attention, and call for more frequent tests and prompt restriction of diet. The value of regular blood pressure readings in all cases of albuminuria was heavily stressed, quite apart from subjective symptoms and albumin estimations, it was the most *valuable clinical guide. Treatment consisted* largely in rest, saline purgation, highly alkaline medicines and dieting—complete starvation in severe cases. A conservative attitude towards the pregnancy should always be adopted, but failure to react to adequate treatment for two or three weeks should be regarded as indicating induction of premature labour. Prognosis depended upon the reaction to treatment, such reaction was best judged by the blood pressure and by the amount of albumin. Oedema was next discussed with special reference to its significance and interpretation. It was so seldom due solely to 'pressure' that such a cause should never be assigned until every other possibility had been explored. The vast majority of cases without obvious local causes such as varicose veins were dependent upon a degree of toxaemia. Careful urine tests and blood pressure readings were essential in the diagnosis and supervision of these cases. Oedema was often the first danger signal in an impending toxaemia, and its importance should be made clear to all expectant mothers. By a scrupulous ante-natal regime that dread disease eclampsia could be almost completely eliminated, but occasional cases of the 'fulminating type' might still occur. Reference was next made to the

dangerous significance of "late vomiting and epigastric pain," and to chronic nephritis complicating pregnancy. The place of induction in these conditions was clearly indicated.

The Ante-natal Examination.

Mr. Eyers then discussed the essential ante-natal examination at the thirty-sixth week, with special reference to malpresentations and disproportion. With regard to malpresentations the following rules emerged: (1) the vast majority of cases were readily diagnosed from an abdominal examination—vaginal or radiological examination being rarely required; and (2) the majority could be corrected by suitable measures. In connexion with occipito-posterior presentations Busst's or Ballantyne's "pad and binder method" was demonstrated. It was commended for the later weeks of pregnancy and during labour. In transverse and oblique presentations the possible causes (such as contracted pelvis or placenta praevia) should always be eliminated, especially in primigravidæ. When such serious causes were found they must obviously take precedence in treatment. All cases should be corrected by external manipulation, and the patient be carefully watched up to full term. Recurrence was always significant, and all such cases should be seen early in labour to ensure safety. Breech presentations should be turned by external version in all possible cases. The ideal time was the thirty-sixth week, but it was never too late to attempt it. Many cases of spontaneous version were encountered between the twenty-eighth and thirty-sixth weeks. Version failed completely in about 10 per cent. of cases, and an anæsthetic was required in about 10 per cent. of the cases. The methods of external version were demonstrated, and the importance of flexing the extended legs to prevent recurrence was fully discussed. Difficulties and complications were mentioned. Of the latter, the speaker had encountered rupture of the membranes on three occasions—placental separation and prolapsed cord twice. External version late in pregnancy sometimes started labour prematurely, practically the only contraindication was placenta praevia. With regard to disproportion and contracted pelvis the value to be placed upon external measurements was discussed, and Mr. Eyers said that too much reliance must not be placed on these alone in either direction. The fit of the fœtal head to the maternal pelvis must be the great clinical guide, and this should always be supplemented by inspection of the pelvic outlet. In a primigravida the head should be engaged in the pelvic brim at the thirty-sixth or thirty-seventh week, failing this, as in a multipara, the head must be fitted to the brim. Where any doubt existed, an internal pelvic examination was called for; when further doubt existed an anæsthetic examination was essential to determine the fit of the head. In a multipara the earlier obstetrical history and the weights of previous babies were of considerable help. The place of induction of premature labour as a prophylactic measure in doubtful cases was referred to. A warning was given against the abuse of Cæsarean section for minor degrees of contracted pelvis. As regards haemorrhage during pregnancy the following rules were formulated: (1) bleeding in a pregnant woman, however slight, necessitates a complete investigation, which must always include a vaginal examination, and (2) cases of ante-partum haemorrhage must be referred immediately to a nursing home or hospital when placenta praevia could not be definitely excluded as the cause, or where there were any signs of toxæmia, such as albuminuria. Only mild cases of accidental haemorrhage, without evidences of toxæmia, could be safely treated in the patients' own homes on expectant lines.

Reports of Societies.

MATERNAL MORTALITY AND MORBIDITY

At a meeting of the Section of Obstetrics and Gynæcology of the Royal Society of Medicine, held on November 21st, the president, Sir EWEN MACLEAN, in the chair, a discussion took place on the interim report of the Departmental Committee on Maternal Mortality and Morbidity. The discussion was opened by Dr. J. Watts Eden and Dr. J. S. Fairbairn.

Dr. EDEN described the general scheme of the report and welcomed the committee's endeavours to ascertain the "primary avoidable factor" in each of the 2,000 deaths which were investigated. This factor was not necessarily the direct cause of death, as in some instances the initial failure was want of any ante-natal supervision. Some interesting facts came out of the inquiry, one being the number of deaths which occurred during normal labour. The occurrence of sepsis in so-called normal labour was very high indeed, and in the majority of these cases no primary avoidable factor could be discovered. In explaining these two crucial subjects—namely, the cause of death in normal labour and the frequency with which sepsis follows normal labour—the report gave no help at all. The committee's recommendations as to the provision of better treatment for cases of miscarriage in hospitals were to be commended. Dr. Eden discussed the training of medical students, and said the schemes put forward by the committee should have the utmost consideration. The increased number of obstetrical cases suggested by the committee for the training of students can only be obtained if the Government and the local authorities are willing to place at the disposal of teachers very much extended facilities both for the training of students and for post-graduates in connexion with the new hospitals which have recently come under the control of local authorities. Such an opportunity may never arise again, and it ought to be utilized to the utmost.

Dr. FAIRBAIRN was impressed with the unanimity of the members of the committee. He referred to other reports where the maternal mortality rate was diminished among the poorer classes, although the general idea was that it was lower among the better-housed and better-fed members of the community. Dr. Fairbairn discussed the social factors in these cases of maternal death and the influence of maternity insurance. He thought that if doctors did not attend cases of normal labour it would be difficult for them to keep themselves up in what one would call the conduct of ordinary normal labour. The health of the patient herself and all her social conditions had to be considered as being of the greatest importance. The relief of pain generally had brought about the consequence that pain is not as easily borne as formerly. The new situation of modern life had to be considered, especially with regard to the maintenance of normal function. This applied to the problem of anæsthetics in labour. Dr. OAKLEY said that the committee could not be blamed for not finding out the cause of maternal mortality. It was appointed first to advise upon the application to maternal mortality and morbidity of the medical knowledge at present available, and, secondly, to inquire into the needs and direction of further research work. It was the aim of the committee to give the Government some practical method which would reduction in the maternal mortality could be effected, and to show the direction in which research should advance. Professor R. J. JOHNSTONE was concerned most with the education of medical students, and the part of the report dealing with this was new. The problems were, Can the teaching schools put these regulations into effect, and if so, will they produce a competent practitioner? These questions had been discussed by Professor Munro Kerr elsewhere.

Lady BARRETT said that the openers of the discussion had brought forward two important points in the report. One was that only in 50 per cent. of the cases was the cause of death found. We must therefore look for the causes of sepsis elsewhere than in contact cases. The other factor was the woman herself, and this should be considered before any other. Practitioners were not necessarily all

perts, but they should have reasonable skill, judgement, and knowledge. Would these regulations ensure the fulfilment of these conditions? It was difficult to get women to undergo ante-natal supervision if it meant residence in a hospital or attendance at a long-distance clinic. The claims of her home were usually her first consideration. Mr. ILLIATT said that the General Medical Council or the examining bodies did not insist on the present regulations being carried out with regard to students conducting twenty cases of labour. Dame LOUISE MCILROY thought the chief value of the report was the crystallization of the opinions of the representatives of societies and of the obstetricians who gave evidence before the committee. She believed that ante-natal supervision should be carried out by trained obstetricians. Mr. DONALD ROY said there was now an opportunity for making a very definite advance towards obtaining the requisite number of cases for medical students. The necessity for more obstetrical beds or facilities elsewhere must be pushed by the medical schools. The welfare of the patient was the first consideration when the administration of anaesthetics was contemplated. Women who were delicately nurtured had more fear of the pain of labour than had the women of the working classes, who were in closer touch with the reality. Dr. THEOBALD was of the opinion that midwives should not be allowed to make vaginal examinations and practitioners should be restricted to forceps application only. Any other operation should be done by a specialist. More maternity hospitals were necessary throughout the country for the admission of complicated cases and for the training of students. Professor BROWNE reminded the meeting that the report was only an interim one. One of the chief problems was the cause of death in normal labour. He had a firm belief in Listerism as a prevention of puerperal sepsis. The whole scheme was based on a recognition of the fact that the psychology of woman had changed, and that she demanded premature intervention because she could not bear pain well. Professor Browne discussed the advisability of the direct responsibility of the teacher in signing up students for examination. The standard of training of the general practitioner was most important.

Mr. COMYNS BERKELEY believed that everything the committee recommended should be carried out with regard to the training of medical students. The additional number of cases required could be found in the hospitals of the London County Council. The PRESIDENT said that the report conformed very much with the opinions generally expressed by obstetric teachers.

THE NEW MERCURIAL DIURETICS

AT a meeting of the Section of Therapeutics of the Royal Society of Medicine on December 9th, with Dr. PHILIP HAMILL in the chair, Dr. EVAN BEDFORD opened a discussion on novasurol and salyrgan.

Dr. Bedford said he had begun to try novasurol in 1920 but had been so unfavourably impressed by its toxic properties that he had now abandoned its use. Salyrgan he had used for the past eighteen months. It contained 36 per cent. of mercury and was given in doses of 1/2 to 2 c.cm., but it was considerably less toxic than novasurol. It was supposed to act by diminishing the affinity of the tissue colloids for water and odium chloride, but in cases of nephrosis it had been found to produce either no diuresis or else much less than the degree recorded when the kidneys were normal, so that it probably acted in part on the kidney as well. The effect of salyrgan was increased by administering alkalis such as ammonium chloride, by mouth. Cases recorded in the literature made it apparent that salyrgan was little inferior to novasurol in its diuretic action and considerably safer, never giving rise to mercurialism if injected in suitable doses. In Vienna the preparation had been used for cardiac oedema, cirrhosis of the liver with ascites, pleural and pericardial effusions, nephritis, nephrosis, and malignant ascites, but the speaker thought its chief value lay in its effects on oedema of cardiac origin. He diluted 2 c.cm. of the 10 per cent. solution of salyrgan with 10 c.cm. of sterile saline solution and injected it slowly into a vein, about ten minutes being allowed for the operation. The fluid intake was restricted during treatment to twenty to thirty ounces daily, but digitalization could continue, and 15 grains of ammonium chloride was given thrice daily by the mouth. Contraindications to the use of the drug were acute nephritis with blood and casts in the urine, and severe diarrhoea, but the existence only of albuminuria need not prevent its use. Among twenty-seven cases of cardiac failure with gross oedema he had only had three failures, and these three patients were *dying on admission*. The effects were equally good whether the heart was fibrillating or failing with normal rhythm. Dr. Bedford quoted several cases in which salyrgan had produced marked diuresis, and in which the weight in some case had fallen between 40 and 50 lb. in four weeks as a result of the loss of fluid.

Professor F. R. FRASER gave his experiences of novasurol which he had found to produce an effective diuresis. Its use, however, was limited by its toxicity, and he doubted whether the benefit produced was of much ultimate value since the patients on whom it was employed were so seriously injured in health as to be beyond any great degree of recovery. He had seen one case of thyroid intoxication with rapid pulse and oedema where novasurol had restored the patient to a condition suitable for operation. Dr. J. STRICKLAND GOODALL thought novasurol one of the most dangerous and toxic drugs ever put into the hands of the medical profession. He showed two specimens taken from the alimentary canal of patients treated with this remedy in which the mucous membrane was haemorrhagic and sloughing. Novasurol in these cases had cleared up both the oedema and the patients. Dr. D. H. KOTTHOF (Vienna) said that the use of novasurol had now been abandoned in Austria. He had seen very good results with salyrgan, not only in cases of cardiac oedema but in cases of nephrosis where the kidney was not seriously damaged, and in cirrhosis of the liver with ascites.

Sir JAMES DUNDAS-GRANT asked whether it was the case that salyrgan had been used in treating patients with Meniere's disease with resultant improvement of hearing. In reply, Dr. WARREN CROWE said that Meakin had used salyrgan in Meniere's disease as a test but not as a form of treatment. The theory was that the cells of the labyrinth were waterlogged in this condition, and about 80 per cent. of the patients showed some degree of water retention. Meakin had found that they reacted differently from the normal patient when given water and salyrgan together; he treated them with calcium diuretics and restriction of fluid and stated that as long as their mouths were dry they had no symptoms of Meniere's disease.

Dr. IZOD BENNETT referred to the experiments of Goverts in Belgium which went to show that the action of salyrgan was largely on the kidney, and that therefore its use in cases where the kidney cells were damaged should be avoided. Moreover, in cases of nephritis with profound albuminuria analysis of the plasma protein showed it to have fallen to about one-half the value found in normal blood, while in cardiac oedema it was normal. In nephritis the osmotic pressure of the plasma protein had fallen so that fluid was less readily drawn into the blood stream from the tissues. It did not appear that the artificial removal of water, either by drugs or by mechanical means, would change a physical condition of blood in which the plasma protein was reduced but such theoretical considerations were not yet sufficiently proven to interfere with the use of effective remedies. In oedema of renal origin where the blood pressure and blood urea were normal he thought salyrgan was useful and probably safe; where there was gross oedema with a high blood pressure and increased blood urea he thought that though it might relieve symptoms the remedy was dangerous because the kidney function was seriously impaired. Dr. J. EAST preferred to use theophyllin and diuretin for cases of cardiac oedema rather than novasurol, which he considered to be too toxic. He had produced an

effective diuresis in one case with salvigan, but the urinary output fell again as soon as the drug was stopped, and it appeared that it must be given regularly to be useful. Dr. A. GAINSBOROUGH said that, although a few patients with nephrosis might recover a large number died from pneumococcal or streptococcal infections, usually after all oedema had disappeared. He wondered whether the advantage of giving mercurial diuretics in nephritis was worth the risk unless it could be shown that they did not shorten the patient's life, he thought they should be avoided.

Dr. BEDFORD replied that he had had several failures in cases of nephritis and nephrosis, and one success where there had been coexistent cardiac failure. He agreed with Professor Fraser that a patient who was seriously ill from cardiac failure was wrecked in health even if he was relieved of his oedema. He added that the patients themselves set a high value on their increased comfort, and attended regularly for treatment with salvigan at his out-patient department. He had heard of the use of salvigan in migraine, but not in Ménière's disease.

THE ACHLORHYDRIC SYNDROME

AT a meeting of the Manchester Medical Society on December 3rd, papers entitled 'The achlorhydric syndrome" were communicated by Dr. T. H. OLIVER and by Dr. JOHN F. WILKINSON.

Dr. Oliver's paper was based on the results obtained after a gastric analysis of over a hundred cases apart from pernicious anaemia in which there was achlorhydria or a marked hypo-acidity. The symptoms fell into two main groups. In the first, the gastro-enterogenous group, there was flatulent dyspepsia with intermittent diarrhoea and constipation of varying severity, and the passage of foul-smelling and badly formed stools. A high degree of neurasthenia was present, and the patients were usually regarded as suffering from neurotic dyspepsia. In the second group a sore tongue or mouth was a prominent feature. There might be either a glossitis with atrophy of the papillae and a smooth shiny tongue, or actual ulceration. Three smaller groups also occurred in which achlorhydria was associated with rheumatoid arthritis with debility and a secondary anaemia, and with skin rashes, usually urticarial. The condition was more frequent in women than in men in the proportion of three to one, and a familial tendency was common. Although the symptoms were usually not dangerous, occasionally severe illnesses might develop in association with it—for example, acute yellow atrophy, Graves's disease, and diabetes. In all these cases the therapeutic results obtained by giving large doses of hydrochloric acid and pepsin were very striking. There appeared to be two types of patients: (1) those with an acid diathesis who tended to develop peptic ulcers but did not develop symptoms associated with intestinal intoxication; and (2) those described in this series with an alkaline diathesis. In the latter the main lesions appeared to be intestinal or they arose from toxic absorption from the intestine, and it was in them that fruits and foods which left an alkaline ash produced an exacerbation of symptoms.

Dr. Wilkinson's paper gave an account of a series of 126 cases examined during the last two years at the Manchester Royal Infirmary. They were divided into two main groups—namely, persistent or recurrent diarrhoea (60 cases) and sore tongue (33 cases). Three smaller incidental groups were defined also: rheumatoid arthritis (15 cases), urticaria (8 cases), and debility (10 cases). The occurrence of gastric secretory impairment was mentioned, and the importance of the fractional method of gastric analysis was emphasized and illustrated by cases. It was indicated that while the usual method of classifying the cases according to the secretion of free hydrochloric acid was convenient and formed a useful basis, there were other estimations equally important such as that of the total chlorides and peptic activities, in the determination of the degree of damage to the gastric secretory mechanisms. It was probable that there were other substances of much importance, not so easily detected. Fractional gastric analyses in the group of 60 consecutive cases with recurrent diarrhoea showed that 29 patients had achlorhydria and 19 hypochlorhydria (less than 10 units)—a total of 80 per cent. with diminished acid secretion. Treatment with a mixture of hydrochloric acid and pepsin was instituted and thirty patients had received continuous treatment for at least six months (maximum two years). The results showed that 89 per cent. of those with achlorhydria were cured, and 5·5 per cent. much improved so long as they continued this therapy while the hypo-acidic cases showed 70 per cent. cured and 20 per cent. much improved. The remaining cases in this group having had less than six months' treatment, were not included in these figures, but all the patients were progressing very well. In the group of 33 cases with sore tongue, 58 per cent. showed reduced secretion (11 achlorhydria and 8 hypochlorhydria). The results of the acid and pepsin treatment gave 100 per cent. cures in those with achlorhydria and 80 per cent. in hypo-acidic cases six to twenty-four months after institution of the treatment. Most of the remainder who had discontinued treatment with a consequent return of symptoms were again relieved by recommencing the acid mixture. In the smaller groups, impaired secretion was found in rheumatoid arthritis (73 per cent.), urticaria and angioneurotic oedema (87·5 per cent.), and debility (80 per cent.). The effect of the acid and pepsin treatment in these cases were discussed. A summary of the results obtained in these 126 cases had shown a total of 74 per cent. with hypo-acidity (44 per cent. of these having achlorhydria), while the proportion of females was four times greater than that of males. The significance of these results and the successful treatment were considered, supported by the familial occurrence of achlorhydria: this absence of acid secretion in the stomach was shown to be an abnormal condition, and probably the first sign in many cases of more serious trouble later. Dr. Wilkinson believed that the finding of achlorhydria in apparently normal persons was an indication for a careful search in such families for diseases with familial tendencies, and discussed the need for prophylaxis against the various conditions.

DEVON AND EXETER MEDICO CHIRURGICAL SOCIETY

AT a meeting of this society held on November 20th, Dr. C. J. FULLER read notes on a case of acute lymphatic leukaemia with cancrum oris occurring in a boy, aged 15, who was admitted to the Royal Devon and Exeter Hospital with a history of painful and swollen gums of seven days' duration. On admission the temperature was 102° F. and the pulse rate 114. The tissues over the lower jaw were swollen and tender but no discoloration of the skin was seen. There was acute gingivitis with small gangrenous patches over the gums on the lower jaw. The upper and lower incisors were loosened and there was marked fetor of the breath. The spleen was enlarged to within 3 inches of the umbilicus, and the liver margin was 1½ inches below the costal margin. The axillary and inguinal lymphatic glands showed moderate enlargement. Tonsillitis was present and Vincent's spirillum was found. The blood count was red cells 2,232,000 per c.mm., haemoglobin 30 per cent., white cells 239,000 per c.mm., of which about 80 per cent. were mononuclear cells of the lymphoid type, which did not give the oxidase reaction. Eventually the gangrene extended to the whole of the gums and to the skin over the chin. Small haemorrhages occurred from the gums and several teeth were cast spontaneously. The boy died about ten days from the onset of the cancrum oris. Dr. J. H. DOUGLAS MURRAY read notes on a case of fragilitas ossium in view of its rarity and of the fact of the association of a recent carcinoma with the onset of the bone lesions. A woman aged 46 had had both breasts removed for carcinoma; the scar over the site of the left breast still tended to break down from time to time. Dr. Murray was first called to see her in consequence of a fracture through the middle third of the right femur, which had happened spontaneously when walking

in the street No previous fracture was known to have occurred and there was no family history relevant to the condition The woman was anaemic but otherwise routine examination revealed nothing abnormal in addition to the scars already mentioned and the fractured femur Two or three days later the patient being immobile on a lung splint, there occurred a spontaneous fracture of the right clavicle With an interval of one week between them similar fractures followed of the left humerus and left clavicle The right femur united with no sign of external callus and the right clavicle with considerable thickening No callus formation was as far apparent in the left clavicle and left humerus Within the previous ten days an unexplained patch of anaesthesia had appeared over the left deltoid but vigilant search for secondary malignant deposits in the bones, or elsewhere in the body had given negative findings Dr Murray thought that if the infection was due to secondary deposits some sign of tumour would have been evident Dr C SEWARD showed a burly labouring man aged 52 with anomalous neurological signs in association with what appeared to be lead palsy There had been a sudden onset with dropping of both wrists last January A history pointing to lead colic was confirmed by a blue line on the gums when the man first came under observation There had been progressive weakness of the muscles of the upper extremity and more recently weakness of the left leg and trunk He was found to have a moderate degree of glycosuria and a true diabetic blood sugar curve There was secondary anaemia, and blood films showed punctate basophilia in an otherwise normal differential leucocyte count The Wassermann reaction of the blood was negative The blood pressure (systolic 120, diastolic 80) was low for his age Dr Seward had found *no sensory changes* but the paralysis was more definite in the antebrachial group of muscles of the left side At the same time all the upper reflexes were absent the left patellar reflex which had been increased at first was now diminished the left leg being dragged on walking Insulin injections the customary antiplumbism remedies and splints for counteracting deformities had not affected the neurological signs which appeared to be slowly progressive and resistant to treatment Dr R N CRAIG thought there was a double pathological process in this case although plumbism could not be discountenanced the symptoms suggested a lower neurone type in addition—progressive muscular atrophy Dr A L CROCKFORD remarked on the very low blood pressure in view of the very high readings usually associated with lead poisoning

DIET AND DENTAL CARIES

A MEETING of the London Association of the Medical Women Federation was held on November 25th with Dr LETITIA FAIRFIELD in the chair After a tribute had been paid to the memory of Dame Mary Scharlieb Mr MAY MELLANBY read a paper on diet and dental caries She said that it was formerly thought that once teeth had erupted their health was dependent on the condition of the mouth This was now known to be only a partial truth Teeth were living structures and as such were dependent on nourishment delivered by the blood stream Discussing the structure of human teeth in relation to dental caries she described her observations on milk teeth The large majority of children's milk teeth were hypoplastic and badly formed and there was an undoubted relation between such teeth and the incidence of caries The presence or absence of vitamin D in the diet affected the arrangement of teeth and the growth of the jaws as well as the structure of the teeth If the vitamin was deficient many other factors became of importance notably the type and quantity of cereal in the food If oatmeal was the cereal taken a large quantity of vitamin D must be taken to counteract it Unfortunately workers had not yet been able to produce caries at will in animals. Discussing the spread and arrest of caries in children Mrs Mellanby showed that the addition of vitamin D to the diet tended to arrest the development of caries when it had started It was not definitely known how vitamin D acted

An animated discussion followed Asked which type of cereal was best for the growing child Mrs Mellanby recommended rice and white flour As regards the source of vitamin D she preferred cod liver oil It could be made available to almost any child in quantities up to 3 4 ounce per day

Reviews.

ATLAS OF PATHOLOGICAL ANATOMY

READERS of the *British Journal of Surgery* will already be aware of the intention of the editorial committee to bring together the supplements which have appeared in that journal during the past few years and publish them in the form of an *Atlas of Pathological Anatomy*.[1] The first volume has now been issued and the committee is to be congratulated on the success of its project The atlas has features which distinguish it from previous works of the kind and are likely to make it of real value to surgeons in their practical work and considering the number and excellence of the plates it is issued at a moderate price that most surgeons will one may suppose wish to have a copy at hand for reference and study Moreover the *figures being remarkably true to nature in colour form* and size it seems hardly an exaggeration to say that as material for study, they are almost as good as the original specimens

The particular features of the work are that the specimens have been chosen to show not merely the anatomical character of the lesion but also their effects on the organ involved and further by means of clinical histories which are included in almost every case to exemplify the physical signs and symptoms to which the lesions give rise The intention has been to produce a work of practical utility and not merely one of interest The arrangement is largely clinical and the subjects have in many instances been chosen because the histories contain features the mechanism of which can be deduced from the study of the specimens The value of the work to those whose circumstances preclude the possibility of access to the museum or post-mortem room for the purpose of supplementing their knowledge will therefore be obvious they have in the atlas a ready means of returning to the bed rock of pathological anatomy upon which the superstructure of medical science has been built up The compilation of the work has been entrusted to Mr E K MARTIN who is presumably responsible for the choice of subject-matter and of the individual specimens depicted and for the general arrangement of the work In addition to his commentaries on the several specimens he has in the case of each division of the subject added an introductory section giving a general account of the lesion and its natural history This is a valuable feature of the work and renders it in a limited sense a textbook of pathological anatomy It should be mentioned that only those lesions are dealt with which are likely to be seen in ordinary practice curiosities and curiosities have been excluded *The successful production of an atlas possessing* these features must depend primarily on the existence of a sufficiently abundant available supply of good material *In this respect the promoters of the work were in the* enviable position of having ready to hand what is probably the finest collection of pathological material to be found in any country and they have not only drawn on the collections of the Royal College of Surgeons of England and the London schools but have brought some of the provincial museums into the scheme many of which now vie with our metropolitan museums in excellence and completeness

It is intended to continue the publication of the atlas until it includes all such subjects as can be profitably illustrated by drawings of museum specimens the present volume deals with diseases of the bones stomach and duodenum breast kidney adrenal gall-bladder and bile ducts It is due to the publishers and to all concerned in its preparation to say that they have produced a work which is a credit to British surgery and to British artistry The beauty of the colour and black-and-white work of Maxwell and Sowell is too well known to need commendation and the same may be said of Ford's accurate

[1] *Atlas of Pathological Anatomy* Compiled by E. K. Martin, M.S., F.R.C.S. Issued under the Direction of the Editorial Committee of the *British Journal of Surgery* Vol. I. Price £1 1s. net. London: Simpkin Marshall, Ltd. 1930. (9½ × 6½ in. pp. 203. 302 illustrations 75 net.)

histological drawings The reproductions, also, are as perfect as one could wish A melancholy interest attaches to the introductory note, which was written by Sir Anthony Bowlby He always took the deepest interest in pathological anatomy and pathological museums, and never lost belief in their importance at a time when their value was in danger of being underestimated The danger has now happily passed, and it would doubtless have been a gratification to him to see the issue of the atlas as at least one evidence of a revival of interest in the subject He has expressed the hope that the atlas may "not only be interesting in itself, but also induce its readers to visit the Hunterian and other museums and become acquainted with those specimens which are too numerous to be depicted in any publication"

WHITRIDGE WILLIAMS'S "OBSTETRICS"

For the sixth edition of his valuable textbook on *Obstetrics*,[1] Professor J Whitridge Williams has found it necessary to revise every page thoroughly, and indeed to rewrite some chapters The revolution which midwifery has been going through under the influence of antiseptic methods and the development of pre-natal care is responsible for some of the alterations, although others, as the author frankly admits, are due to a change in his opinions brought about by the growth of experience He has spent a lifetime in thinking over the many problems of normal and abnormal midwifery, and has taken nothing for granted but has tested for himself and considered every method of treatment advocated Thus credit is given to every obstetrician who has helped to improve the art, and the extensive bibliography at the end of each section will be valued by all serious students of midwifery A feature of the book is the author's emphasis on the conservative aspect of this branch of medicine surgery, he maintains, should be invoked as an aid to the obstetrician only when purely obstetrical methods have been found not to give entirely satisfactory results The chapters on special anatomy and physiology, and on the development of the ovum have been carefully revised and brought up to date, and are accompanied by excellent illustrations The practical bearing of the information is kept well to the front At first glance it is rather surprising to find that only six out of the 1,157 pages are devoted to the subject of pre-natal care but the explanation is that details of this work will be found under other headings It would, however, be more convenient, even at the cost of some repetition, if some of this information could have been brought into the chapter on the management of pregnancy We miss the name of Ballantyne, one of the pioneers of ante-natal hygiene Some of the terms used differ from those in common use in this country, and this may lead to misunderstandings

The toxæmias of pregnancy are fully considered, and an attempt is made to evolve some sort of order out of chaos by a tentative classification of the toxæmias accompanied by albuminuria into three types—namely, "low reserve kidney" 'pregnancy complicated by chronic nephritis" and 'pre-eclampsia" Contracted pelvis is very fully described, but the treatment recommended seems hardly to warrant the long description or the meticulous pre-natal care upon which the author insists, and many will feel that although he dismisses it with scorn, induction at or about the thirty-eighth week, which often gives excellent results to both mother and child, has a definite place in the management of pregnancy with contracted pelvis The methods of treatment for other abnormal conditions differ from those usually adopted in this country Thus no mention is made of bimanual compression of the uterus for post partum hæmorrhage In accidental hæmorrhage the advice is given to perform Cæsarean section in all cases that cannot be terminated at once, which is surely not intended to be taken literally, seeing that the majority can be treated successfully by expectant methods From these few criticisms it will be clear that in our opinion this is a textbook that must be recommended with some reserve to the English medical student preparing for a pass examination but it has very great value as a scientific treatise setting forth the data, and summarising in a judicial manner the arguments upon which the practice of midwifery at the Johns Hopkins Hospital has been developed by one of the makers of modern obstetrics

THE PHYSIOLOGY OF THE VESTIBULAR APPARATUS

The first experimental observations on the functions of the semicircular canals were made over one hundred years ago by Flourens, who followed a sound principle in physiology—namely, that the first rule for elucidating the function of an organ is to destroy it and observe the effect on the organism He narrowed his researches from destruction of the whole labyrinth to division of separate canals He noted the tumultuous movements which resulted from the operations, and that these movements have as many directions as there are cardinal or principal directions The originated the conception that the semicircular canals are the seat of forces which influence the movements of the head It was not until the seventies that Goltz and Stefani made further experiments, and concluded that the semicircular canals are the specific organ for the sense of position of the head, whilst Breuer, Mach, and Crum Brown, as the result of their researches, produced the theory that the semicircular canals serve for the perception of angular accelerations Cyon also, in the late seventies made numerous experiments, and studied the connexion of the semicircular canals with nystagmus In the eighties Ewald proposed that the semicircular canals are responsible for the maintenance of tone in skeletal muscle Cyon also drew a striking analogy between the function of the labyrinth and the rudder of a ship This constitutes a second period in the history of the physiology of the labyrinth, in which little further progress was made except by Barany, until the work of Sherrington prepared the ground and provided a technique for the famous researches of Magnus and de Kleyn These are based essentially on the classical methods for the investigation of reflex activity Thus the righting reflexes, which are on the head, cannot be studied in a decerebrate animal but persist in a thalamic preparation, with the decerebellum intact They are lost when such an animal is deprived of its labyrinths The researches of Magnus and de Kleyn, with numerous fellow workers at Utrecht embrace an enormous number of experiments and observations which have thrown fresh light on the functions of the cerebellum, as well as on the vestibule and its central connexions This stage brings our knowledge of this branch of physiology up to its present position

This slight sketch is necessary to indicate, however imperfectly, the scope of *The Physiology of the Vestibular Apparatus*,[2] by Mario Camis of Parma, translated by Dr R S Creed of New College, Oxford It follows the historical method, and presents the solution of an extraordinarily complicated physiological problem with great lucidity It embraces also much that has not been mentioned, such as the question whether the semicircular canals possess acoustic sensibility, and the author's own researches on the vestibular visomotor reflexes, and even touches on the doctrines of Kant The book, however is in the main inspired by the work of Magnus and de Kleyn, based on Sherrington's conception of reflex activity There is no work in English which makes any attempt to cover the same ground, and therefore physiologists, neurologists, and otologists will be grateful to Dr Creed for this fascinating translation Camis seems to include everything worth recording, and studies the problem from every aspect, so that there is much that is stimulating and controversial The reader is taken through this maze by an unerring guide, who conducts him to the conclusion stated on page 186, where the functions of the ampullæ of the semicircular canals and the maculæ of the sacculi and utricle are finally synthesized after this long analysis

[2] *The Physiology of the Vestibular Apparatus* By Mario Camis Translated and annotated by R S Creed B M B Ch Oxford The Clarendon Press 1930 (6½ × 9½, pp xiv + 310 65 figures 21s net)

he author however, as he makes clear in the epilogue under no illusion that the reflexe observed in decerebrate or decerebellate preparations indicate all the paths followed by labyrinthine impulses in the normal animal he central connexions of the vestibular apparatus are o complex that it is impossible to isolate the labyrinthine unction in the intact animal

It has only to be added that the Clarendon Press presents he volume in a form which makes it a pleasure both to ead and to handle

SCIENCE TEACHING IN SCHOOLS

A volume entitled *Teaching Science in Schools*[1] by John Brown, formerly inspector of schools under the London County Council, is an important book It was first published in 1925 and a second edition has just been issued Its theme is based upon the proposition that science teaching in our schools to-day has become too narrow, too routine, too uninteresting too unpractical, and that it is therefore in urgent need of development on new and more rational lines in order to give it a broader more human and more lasting appeal This proposition is true but it is only now being occasionally admitted by teachers, and has scarcely anywhere led to any practical change For many years now school science teaching—more particularly the teaching of chemistry and physics the only sciences usually taken in boys schools—has been conducted upon the theory that pupils are to discover everything for themselves and to be told nothing and that accurate measurements and quantitative results are the primary essentials The consequence has been," says Mr Brown "that experiments are done merely for the sake of doing them, and those sciences which do not involve measurement and quantitative work have been completely neglected" Most pupils will not become scientists but require a general education which is incomplete if it does not include some acquaintance with natural phenomena, physical properties and laws and the applications of scientific principles to everyday life The bulk of the small volume is however not critical but constructive and the author shows how the necessary reform of method and scope can be carried into effect with various types of scholars and of schools Not only is his thesis important but his suggestions to teachers for whom the book is primarily intended, are very practical and valuable

TREATMENT OF ASTHMA

The literature of medicine is overburdened with works purporting to solve the problems of what Dr A H Douthwaite terms 'the mysterious malady Asthma research organizations have been established in many countries, the specialist, the general practitioner the biochemist and many others have joined battle against an unusual and well-equipped adversary still the tumult and the shouting" show no sign of dying down It is therefore a relief to take refuge in the comparative quietude of Dr Douthwaite's short and well reasoned treatise entitled *The Treatment of Asthma*[2] In point of fact, less than half the book is devoted to treatment proper, the first eighty pages summing up the factors which are generally regarded as constituting the asthma diathesis There is evidence throughout of careful consideration of both theory and fact The author succeeds in his effort to present an up-to-date summary of the most difficult subject, and he will save the student much laborious searching through the vast literature now in existence With regard to treatment he lays special stress on physiotherapy and vaccines as methods of relief, and describes the exercises which are intended to produce mobilization of the chest wall and shoulder girdles Acknowledgement is made of the success which has resulted at Cure's Hospital under the supervision of Miss Angove from rhythmic exercise accompanied by gramophone music

NOTES ON BOOKS

The second volume of the twenty ninth and thirtieth edition of the Strumpell Schwarth Textbook of Special Pathology and Therapeutics[1] has rapidly followed the appearance of the first to which we drew attention in our issue of August 2nd (p 184) The present volume is devoted to diseases of the urinary system locomotor disorders including acute and chronic rheumatism and acute poliomyelitis diseases of the blood endocrine disturbances metabolic disorders avitaminosis and allied conditions and diseases of the nervous system There are three appendixes dealing respectively with the important intoxications prescriptions and baths and spas respectively The present edition has been well brought up to date the text being freely interspersed with excellent reproductions of photographs diagrams and charts

Dr Jacques Viet's well-documented work on the insane and criminal at Saint Lazare in the seventeenth and eighteenth centuries is divided into three parts dealing respectively with the history of this celebrated Paris prison during the period 1632–1789 when it was exclusively reserved for men with the administration of the prison including the principle and object of detention therein and with illustrative cases Throughout the Middle Ages and until the beginning of the seventeenth century Saint Lazare served as a leper hospital but in 1632 it was handed over to the Congregation of Priests of the Mission headed by St Vincent de Paul who organized it as a house of detention for members of the upper classes suffering from mental or moral infirmities the former including melancholia psychasthenia periodic psychoses dementia praecox and general paralysis and the latter various anti social acts such as drunkenness indecency theft cheating crimes of violence and even murder St Vincent instituted a method of psychotherapy which was applied to both these groups and consisted in isolation silence and a series of intellectual exercises supplemented by individual encouragement and collective address

In The Ferments[2] a study emanating from the physiological laboratory of the Medical Faculty of Paris and introduced by a preface from the dean of the faculty Professor C H Roger (who has shown his keen interest in the subject by a number of papers) Mlle Yvonne Schaeffer first gives a sketch of the present state of knowledge about ferments in general, and then considers in greater detail the three animal ferments—invertase trypsin and lipase On each of these agents she has carried out chemical investigations which are discussed with full knowledge of the work of others Her conclusions are clearly tabulated and appended to her monograph there is an extensive bibliography

PREPARATIONS AND APPLIANCES.

A Modified Thomas Knee Splint

Dr E Scott (Ashford Kent) writes The accompanying illustration represents a modification of the Thomas knee splint The front portion of the pelvic ring is hinged externally so that it will open and swing outward It fastens internally with a pin which fits into a slot and is held firm by means of a strap When the ring is opened the splint can be slipped under the patient's leg instead of being threaded on in the usual way Painful manipulation in the case of the recent injury or the acutely inflamed joint are thereby reduced to a minimum

The splint has been made for me by Mr J H Montague 69 New Bond Street W 1

Press

Messrs Cow and Gate Ltd have sent us a sample of a new rusk which is said to be suitable for young children It is light, therefore encouraging mastication without causing pain in the child mouth It is palatable and crisp and of handy size

THE 1930 PILGRIMAGE TO MECCA

A RECENTLY published report[1] gives the details collated by the Egyptian Council of Maritime Sanitation and Quarantine in connexion with the 1930 pilgrimage to Mecca. Dr J. Gilmour, president of the council, notes in his introduction that 84,821 pilgrims came by sea, and 23,776 passed through Egypt *en route* to the Hedjaz. The religious ceremonies at the Holy Places began on May 8th and ended on May 22nd. Time holds small place in Oriental calculations, for pilgrims had already begun to arrive in Egypt during November, 1929. A general survey of the whole report shows that there was remarkably little disease, and this happy result can be placed to the credit of the measures advised in the International Sanitary Convention of June, 1926, and the resolutions adopted by the Beirut Conference of January, 1929, which were closely observed by the sanitary authorities this year, particularly in managing the transit of pilgrims through Syria and Iraq. Not only in Egypt, but in most of the countries of origin, vaccination was more generally practised, notably in India, where all the pilgrims embarking at Karachi were compulsorily vaccinated. The majority of these countries followed the precepts of the 1926 Sanitary Convention with regard to the general measures necessary for the management and transport of the pilgrims, and a hint is given to those authorities who have not yet conformed that it would be well for them to do so in the near future.

The Approaches to Mecca

The avenues of approach to Mecca are dealt with in the earlier chapters, and from them can be gathered the thorough way in which the whole traffic of this annual religious migration was directed. Pilgrims who cross Egypt are of three classes: (1) those who pass through the Suez Canal on board pilgrim boats, (2) those who arrive at Kantara, Port Said, and Alexandria, and, having crossed Egypt by land, make for Suez, where they are embarked for the Hedjaz, (3) Egyptians and resident foreigners in Egypt who embark at Suez on Government-hired steamers. Among these three classes are Algerians, Moroccans, Persians, Turks, Bulgars, Russians, Afghans, and Albanians. All the vessels employed for the transit are specifically hired for the outgoing and return journeys, and are under medical surveillance. The council does not approve of such vague diagnoses of death as marasmus, senility, myocarditis, furnished by some ship surgeons, and will try to have this matter made more definite in future. Such diagnoses can well hide the actual fact of death from cholera. While 23,776 pilgrims embarked at Suez or passed through the Canal, by far the greater proportion, 52,408, came by sea via Kamaran; there were also 4,888 who crossed over from Suakim. Indians, Javanese, Kurds, Chinese, Zanzibaris, Senegalis, Afghans, Bokharins, Soudanese, and South Africans from Capetown used the southern sea route. All these pilgrims had submitted to anticholera inoculations. In spite of the general Jennerian vaccination, *four vessels which were small-pox-infected* arrived at Kamaran. A quaint concomitant of modern conditions lies in the fact that of 40,000 pilgrims who visited Medina (a holy place north of Mecca) before the actual pilgrimage to the Holy City, 25,000 went by motor cars and only 15,000 by the time-honoured method of caravans.

Supervision of Pilgrims

From the moment of arrival at the Hedjaz till the return from the Holy Places the pilgrims were under a complete system of sanitary supervision. This entailed a vast *travail intensif*. Electricians, plumbers and other workmen, supervised by the chief architect of the Administration, constructed new buildings, houses, isolation quarters, hospitals and latrines. Plentiful supplies of water were arranged and disinfecting apparatus and laboratories were established. On debarkation the pilgrims passed to sorting-houses where their baggage was examined and then linen disinfected by steam, all leather articles were fumigated by formalin vapour, and vessels containing water taken from the Holy Wells were boiled. From the sorting-houses the travellers were placed by lots of fifty in a disrobing room. Each individual received a small iron box in which to place personal valuables, and after undressing, was given a linen gown and passed on to the baths. The report gives figures and drawings of the steam pressure stoves and the methods taken to make the pilgrims as non-infective as possible. Details are given of the cases treated in hospitals, which were in touch with bacteriological laboratories. Antimalarial precautions were observed in all the encampments.

Cholera Research at Tor

A most important part of the report deals with the work of the laboratory at Tor, it is written by Dr. W. Doorenbos, director of the quarantine council's laboratory, Alexandria, who was in charge of the Tor encampment during the pilgrimage. He deals at length with the vexed question of true and pseudo-cholera, and confesses that in spite of all the work already done on the subject there is still much confusion on the diagnosis of the different strains of vibrios. The result of his labours is that he has been able to make certain deductions which will serve as the basis for future work. Of 20,730 stools examined at Tor the number of vibrio strains isolated was forty-six, of which two were agglutinants and forty-four non-agglutinating. The two former had been inoculated against cholera before their departure for the Hedjaz, while of the forty-four non-agglutinants thirty-nine had evidence on their cards, and in the remaining five this information was uncertain. After describing the methods of isolation and the histological properties of the vibrios, Dr. Doorenbos proceeds to discuss general considerations on the variable morphology and agglutinable characters of the true cholerae vibrio as compared with the pseudo variety. This question has troubled quarantine authorities in India and all over the East. Endeavours have been made to establish the same relationship as between typhoid and paratyphoid, and in the Special Report, No. 51, of the Medical Research Council mention is made of a disease having symptoms like those of cholera, though usually of mild type and followed by a lower case mortality.

> "The vibrios recovered from such outbreaks, though have a general resemblance to the *V. cholerae* in their morphological cultural characters, are serologically quite distinct. These organisms have been termed *V. paracholerae*."

Dr. Doorenbos's comment on this is that if he has a case in which the vibrios present are morphologically and culturally identical with the *V. cholerae*, he diagnoses cholera, even if there are some differences in the agglutinating power of the different strains. Because of the forty-six vibrio cases found in pilgrims coming from places related to epidemic centres in India, the whole pilgrimage was considered cholera-infected and a subsequent case of true cholera at Massowa confirmed the conclusion. While it is admitted that there are no means of bacteriologically determining that a vibrio is or is not that of true cholera it was decided that in each case where a vibrio is isolated it should be considered suspect. This considerably increases the number of such cases, even although among them will be found degenerated vibrios which are not pathogenic to man. Nor can the haemolytic powers of agglutinating cholera vibrios serve to identify a strain, for, as shown by Dr. Marra at Port Said, some strains that have given proof of haemolysis when examined six months later had lost that power.

While the report cannot, therefore, be said to bring any new light on this important subject, it summarizes in concise fashion much of the previous work, and adds fresh observations of value. The Egyptian Maritime Sanitary and Quarantine Council is to be congratulated on the comprehensive and efficient way it manages this annual pilgrimage, a cohort of more or less irresponsible and potential spreaders of epidemic diseases from the sub-areas of Africa and the Near and Far Orient. A study of the report shows the steady advance which is being made in co-ordinating the work of international public health and epidemiology, and the willingness of different countries to carry out inoculation and other measures to prevent their nationals from embarking as far as possible in other than non-infective condition.

SATURDAY, DECEMBER 20TH, 1930

RECENT WORK ON YELLOW FEVER.

At the beginning of 1913 the Secretary of State for the Colonies appointed a commission to study the nature and relative frequency of the fevers occurring among Europeans natives and others in West Africa especially with regard to yellow fever and its minor manifestations This commission under the chairmanship of Sir James Kingston Fowler lasted for approximately three years its fourth and final report being dated March 31st 1916 In the light of recent discoveries it is interesting to refer to the general conclusions and recommendations of that commission embodied in their four reports and also in the volumes dealing with their investigators reports Probably owing to the fact that these reports were issued during the war they have not received the attention they deserve for most of the recommendations and conclusions of the commission have been abundantly justified by subsequent events Their conclusions to the effect that yellow fever is an endemic disease on the West Coast of Africa and maintained by the existence of endemic foci has received a striking confirmation in a recent publication of the Rockefeller Commission in West Africa[1] Drs Beeuwkes Bauer and Mahaffy members of this commission collected samples of blood from the natives of various towns in Nigeria and Sierra Leone and by means of protection tests in monkeys determined what proportion of the natives had suffered from yellow fever In the densely populated towns of Ibadan and Ilorin in Southern Nigeria out of 125 serums collected at random 30 4 per cent contained immune bodies against yellow fever and in Ife where an epidemic had recently occurred, 17 out of 25 or 68 per cent were protective On the other hand on the plateau of Northern Nigeria only 1 out of 90 examined was positive Similarly in Freetown where no yellow fever has been reported since 1910 only 1 out of 34 gave complete protection These observers also found that at least 1 out of every 4 young children in Ibadan and Ilorin had had an attack of the disease although no child under 5 years ever presented a clinical picture justifying the diagnosis of yellow fever It is evident therefore that this densely populated region of Southern Nigeria constitutes a great endemic centre of the disease where the native is as saturated with yellow fever as he is with malaria The infection is maintained among the infants who constitute the local non immune population and on whom the disease seems to have very little effect Such infected children serve to maintain the infection in the mosquitos and in this way the disease may persist for long periods without its existence being recognized With the influx of numbers of non immunes such as Europeans or natives from uninfected regions there is always the possibility of an epidemic being produced especially when the number of mosquitos is allowed to increase

The transmission of yellow fever has been the subject of an important paper by Professor Edward Hindle the Beit Research Fellow in Tropical Medicine who has been studying this problem at the Wellcome Bureau during the past two years It has been generally assumed that this disease is transmitted only by the bites of the yellow fever mosquito (*Aedes aegypti*) but experiments in both West Africa and South America have shown that other species of mosquitos may carry the disease Consequently Hindle suggests that in the endemic centres of West Africa antimosquito campaigns should be directed against all mosquitos indiscriminately Although as he has shown a mosquito once infected generally remains infective for the duration of its life and in one experiment was still infective 118 days after feeding on a yellow fever patient no evidence was obtained in support of the view that the infection is transmitted to its offspring Therefore by intensive antimosquito campaigns, it should be possible to eradicate the disease from West Africa in the same way as it has been eliminated from North and Central America A hitherto unsuspected mode of transmission has been brought to light in the course of these experiments During the early stages of the disease the blood of yellow fever patients is highly infectious and if the surface of the skin becomes contaminated with such blood infection may result Two cases are described in which the patients could have acquired the infection in no other way than by contamination of the skin whilst handling infected blood and who had never had the opportunity of coming in contact with infected monkeys or mosquitos One of these patients became infected after merely doing a blood count on another case therefore in view of the common occurrence of haemorrhages during the course of the disease it seems likely that yellow fever occasionally may be spread directly by these means The danger is probably not very considerable as the blood often ceases to be infective before such clinical signs as haemorrhages have appeared but there would be a possibility of hospital staff and attendants acquiring the infection whilst handling patients in the early stages of the disease and especially during any blood examinations In the past all study of yellow fever has been conducted in endemic regions and any infections have been attributed to the bites of infected mosquitos but there can be little doubt in view of these results that direct infection must have occurred, especially in hospitals Although the blood of human patients is highly infectious during the early stages of the disease and may contain up to 100 million lethal doses per cubic centimetre there seems to be a rapid production of antibodies even in fatal cases and as a result the blood generally ceases to be infective by the third or fourth day of fever and sometimes earlier Consequently there is little risk of acquiring the infection when performing necropsies on human yellow fever cases but in monkeys owing to the more rapid course of the disease this is not so and the blood and tissues are often infective at death

The main facts governing the transmission of yellow fever now seem to be fairly well established but hitherto as in the case of all diseases due to ultramicroscopic viruses specific chemotherapeutic treatment has entirely failed With the object of finding some efficient treatment for the disease G M Findlay and E Hindle[2] have been studying the changes in the course of yellow fever and found they showed a close similarity to those occurring in other conditions involving liver necrosis such as carbon tetrachloride chloroform or arsphenamine poisoning One of the most striking changes in these cases is an increase in guanidine like substances in the blood, and the toxic symptoms associated with guanidine

[1] *Amer J trop Med* x 05-333
[2] *Lancet* October 18th 1930.

[2] *Lancet* September 27th, 1930.

poisoning present certain resemblances to the symptoms observed in yellow fever patients. Analyses of the blood of monkeys infected with yellow fever showed that the guanidine content increased to approximately double the normal quantity. The increase could be reduced to normal by the administration of calcium lactate, but it was necessary to give repeated injections because the effect of the calcium did not last for more than a few hours. It is disappointing to have to record that in spite of this apparent success, calcium lactate did not prevent death in the monkeys suffering from yellow fever, although it did tend to prevent haemorrhages, and is evidently of some value in the treatment of the disease.

METABOLISM OF TUMOURS

It is now seven years since Professor Otto Warburg began his researches on the metabolism of tumours. In the interval he has published a number of papers on that subject, and it must have been the experience of many of those who followed the account of his investigations that the precise significance of his results was not realized without some difficulty. A short, final article of two pages, however, which he published in 1929, removes all obscurities when read in conjunction with the previous articles. The publication of the whole series in a single volume was subsequently undertaken, and an excellent translation of this work—*The Metabolism of Tumours*—has now been provided by Dr. Frank Dickens.[1]

One of the recognized characteristics of tumours is irregular growth, it was Professor Warburg's task to construe the latter in terms of irregular metabolism. The sources of growth energy being oxygen and carbohydrate, utilized respectively in the processes of tissue respiration (oxidation) and fermentation (glycolysis, or the splitting of carbohydrate into lactic acid and CO_2) the research consisted in ascertaining and comparing the quantitative variations of these two processes in normal and tumour tissue, and in defining the mutual relationship if any, existing between them. The twofold function is inherent in all cells, actually or potentially. A full description of the technique employed is given in Professor Warburg's book, it is sufficient to state here that the amount of respiration is measured by the amount of oxygen absorbed by a given weight of tissue in a given time, and the amount of glycolysis by the quantity of CO_2 produced. By saturating the culture medium with nitrogen, and thus excluding oxidation it becomes possible to study *the glycolytic function in isolation* (anaerobic glycolysis). By this means it is found that all tissues possess a potential glycolytic function, varying in amount in proportion to the proliferative activity of the cell at the time of observation. In stationary connective tissue it is barely recognizable, in non-malignant tumours it is moderate in amount, in rapidly proliferating tissue it is abundant, as in the embryo and malignant tumours which exhibit a practically identical glycolytic activity.

Thus as regards the *amount of potential glycolytic function* Professor Warburg finds nothing abnormal in tumours—it is that of normal tissue in a corresponding condition of proliferative activity. As regards the mutual relationship of the two processes within the cell oxidation appears to predominate over, and as a rule suppress, glycolysis, which, however, is always resorted to under conditions which exclude oxidation. An observation of Pasteur's furnishes a good example of the suppression of the glycolytic function by oxidation, he showed that yeast fermenting under anaerobic conditions relinquishes the glycolytic function on the admission of oxidation, thenceforward deriving energy from the latter. There are, however, exceptions to this rule of suppression, instances are met with in which glycolysis is present in association with oxidation (aerobic glycolysis), and it would appear from this fact that the dominating influence of oxidation is not direct, but is exercised through some intermediate chemico-physical reaction ("Pasteur reaction" Warburg proposes to call it), which may, on occasion, be absent, and the failure of which renders the influence of oxidation on glycolysis nugatory. If this reasoning is correct, the simultaneous existence of the fermentative and the oxidative processes in a tissue indicates that there is a disturbance of the function of tissue respiration—the oxidative process is unable to proceed on normal lines. Professor Warburg has shown that tumour tissue exhibits this aerobic glycolysis, and therefore concludes that its respiratory function is irregular. Aerobic glycolysis is, however, by no means specific for tumours, it may be induced in normal tissues if suitable means are taken to obstruct oxidation, as Warburg has shown in several of his experiments. But there is a marked difference between the behaviour of normal tissue and that of *tumours in these circumstances, normal cells* inevitably die, while the cells of tumours not only survive, but *are able to grow to an unlimited extent* turning to account the chemical energy of glycolysis. This power of survival under the condition of aerobic glycolysis is therefore the essential characteristic of tumours, as compared with normal tissue and is regarded from the point of view of metabolism.

It may be asked what light these researches throw on the problem of the causation of tumours. It has been mentioned that the degree of glycolytic activity is found to vary in proportion to the rapidity of tissue growth, glycolysis, actual or potential, therefore *appears to be closely connected with growth. To conclude* from this fact, however, that the assumption of *a glycolytic type of metabolism is the cause* of tumour formation would obviously involve the danger of falling into a logical fallacy. Tumour formation may be due to quite other causes, which may conceivably bring aerobic glycolysis in their train. The researches do not, in fact, bear directly on the problem of causation but they have added an important detail to our knowledge of the peculiar features of tumour growth—a valuable acquisition, since it opens up a new avenue of approach in the study of the causation of tumours.

EARLY LABORATORY DIAGNOSIS OF TYPHOID FEVER

It is common knowledge that the Widal test, *as ordinarily* performed, fails to give a positive result in some cases *which seem clinically to be of enteric fever*. According to Dr. A. D. Gardner of the Standards Laboratory, Oxford, whose work is discussed in the last annual report of the South African Institute for Medical Research,[2] investigations by Muñoz (1897), Smith and Reagh (1903-4), Walker (1903, 1918), Arkwright (1921), Weil and Felix (1920), Andrews (1922) and others, have all contributed to the recognition of one reason for this failure—namely, the *fact* that there exist non-motile strains of the typhoid bacillus. It is now well known that a typhoid fever serum which successfully agglutinates non-motile bacilli may fail to

[1] *The Metabolism of Tumours.* Edited by Otto Warburg. Translated from the German edition with accounts of additional recent researches by Frank Dickens, M.A., Ph.D. London: Constable and Co., Ltd. 1930. (40 net.)

[2] Annual Report for the year ended December 31st, 1929. Johannesburg. 1930.

agglutinate the motile organisms ordinarily used in carrying out the Widal test. The non-motile strains possess what is now termed the O type of antigen and accordingly produce O agglutinin only; the motile bacteria on the other hand possess two kinds of antigen termed H" and O" which stimulate the production of both types of agglutinin. Recently Felix has elaborated a qualitative method for demonstrating agglutination of one or other type in the serum of enteric cases and confirmation and extension of his work have been recorded by Gardner and Pipper. Gardner believes that if inoculation can be excluded the O agglutination diagnostic test need be applied only when the ordinary H" test has given negative or doubtful results. It may also be used in the early or late stage of cases in which a diagnostic H' test has failed to develop or having done so has disappeared. It is not possible however, by the O' agglutination test to identify the infecting species for the O substance is not specific. In the experience of the South African Institute for Medical Research a further reason for the failure of the Widal test lies in the fact that a number of the specimens of blood or serum submitted for Widal testing have been taken from patients during the first week or nine days of the illness a period in which blood culture offers a surer means of diagnosis. In many cases however the practitioner finds it far more difficult to collect blood for culture than for Widal testing and this difficulty has probably stood in the way of the more extensive use of the blood culture method. Recognizing this possibility the institute has been supplying on request small rubber-capped bottles containing sterile ox bile the advantages of which as a culture medium are that the typhoid bacillus flourishes in it to the exclusion of contaminating organisms that may be introduced fortuitously. Experiments have shown that typhoid bacilli may be isolated from this medium even when it has been inoculated with no more than 0·2 c.cm. of blood from a typhoid patient. Evidence is accumulating at the institute that the dual method of arriving at a diagnosis may be applied to specimens collected even in the early stage of typhoid infection. The procedure adopted is to withdraw the separated serum for agglutination tests and then to introduce the clot into tubes containing ox bile. Positive cultural results have been obtained in this way from specimens collected between the fifth and ninth day of illness by practitioners living a long way from the laboratory. In such cases the institute has adopted the practice of reporting first the result of the agglutination test and then a few days later the result of the cultural test.

MEDICAL RESEARCH IN HAMBURG

For some reason the facilities offered in Hamburg as a medical centre are insufficiently known in Great Britain so that study tours to Germany seldom include a visit to a university city which is actually nearer and more accessible to this country than Berlin, Munich or Heidelberg to name a few favourite centres. In a recent volume[1] dealing with the whole question of research institutes compiled by many authors Professor Ludolph Brauer describes the medical research work carried on at the large Eppendorf Hospital in Hamburg where 3,000 beds distributed in many pavilions offer remarkable clinical opportunities. The receiving wards are visited twice daily by a member of the staff who allocates the patients to the various departments of the hospital; by attending these visits the investigator of any particular problem is kept in close touch with the available clinical material. Laboratories for all aspects of medical research are in close contact with the wards and the clinical workers in the various departments are almost as much at home in the laboratory as in the wards. The special departments available for the study of particular problems are many. The German Research Institute for Tuberculosis stands in close proximity to the ward set apart for pulmonary tuberculosis and other lung diseases. Here "working places" are available on lines similar to those at the zoological station at Naples for example and investigators can obtain expert guidance in their work. In order to study the many problems of climate high altitudes air etc. connected with the treatment especially of lung disorders the Eppendorf Hospital has lately added two elaborate pneumatic rooms to its research equipment. Each of these completely air-tight rooms has a floor space of 12 by 15 feet and is 9 feet high. The walls are strongly built with steel rods to reinforce the brickwork and a pressure of three-quarters of an atmosphere above or below normal can be safely withstood. Strong pumps can produce this change of pressure if necessary in twelve minutes and it is arranged that a stream of nearly 500 cubic metres of filtered dry air can be circulated through each room every hour. Air locks through which food can be passed into the room, telephone communication between the occupants of the rooms and those in charge of the apparatus and careful control of the temperature and water-vapour content of the air by means of electrically recording thermometers make these pneumatic chambers valuable additions to the scientific resources in Hamburg both for treatment and scientific investigations. Institutes for cancer research for the investigation of problems of light for clinical pharmacology and for colloidal biology deal with special aspects of medical research. A well-equipped diet kitchen in a modern building with two large and several small ward analytical laboratories metabolism laboratories etc. afford great opportunities for the study of metabolic problems. The daily diet of between 100 and 120 patients is carefully prepared according to scientific standards and lecture courses in dietetics are held for doctors nurses and students. The surgical treatment of diseases of the lungs can be studied particularly well in a hospital directed by such a pioneer in this subject as Brauer and thoracoplastic work can be followed in its various aspects. The Eppendorf Hospital has many well known names connected with its staff; a bust of Curschmann stands just within the entrance gate not far from the dermatological clinic which Unna used to direct. The names of Nonne in the neurological Fahr in the pathological and Much in the tuberculosis departments are universally known. Professor Brauer's account of the research departments and hospital which he directs makes it clear that here is a well-organized unit in which clinical research is the normal method of work because the clinicians have a strong scientific background and the laboratory workers are always close to clinical material.

PROPOSED INTERNATIONAL SCHOOL OF HEALTH STUDIES

THE French Government continues to show a praiseworthy initiative in encouraging what some would call the incidental or contingent activities of the League of Nations. It was on the suggestion and with the help of the French Government that the International Institute of Intellectual Co-operation was established in Paris a few years ago; recently the French Government has made another proposal which however has yet to be ratified by its Parliament—namely that there should be established in Paris under the direction of the Health Committee of the League an international school of advanced health studies. The school if it materializes will be maintained by an annual grant of a million French francs (rather more than £8,000), and its object will be to meet the need for an institution where knowledge of the best modern practice and research work

may be obtained and the methods of different countries compared The suggestion really arises out of the organization by the League of Nations of the very useful system of interchanges or study tours for public health officials, whereby the officials in one country have been enabled to see what other countries are doing in the same or parallel fields In connexion with these interchanges, courses of study have been organized in London and in Paris, where instruction has been given by teachers from a number of countries and the value of these experiments has been so evidently proved that a demand has arisen for something more permanent and systematic, whereby all national health administrations choosing to do so could benefit by each other's knowledge and experience The school will also afford an opportunity for directors of schools of public health in different countries to meet regularly and to discuss their common problems Both the teachers and the students of the school will be picked men and women drawn from different countries it is expected that the students will generally be selected by their national authorities, and that in due course various scholarships and subsidies will become attached to the international school The courses will lay emphasis upon a comparison of the practice in various countries with regard to health matters, and the points of divergence There will be field work and discussion groups as well as lectures The theoretical programme will be divided into three principal branches—namely, comparative general hygiene, an outline of the fresh knowledge acquired in the sphere of health and of related sciences, and the organs and method of international health co-operation The framing of a plan for the school was one of the chief pieces of work at the meeting of the Health Committee of the League of Nations at Geneva in October The Health Committee, whose members will compose the governing body of the school, with a director appointed by the French Government, has recently, by the way, been reconstituted and enlarged Its members, who are appointed for three years, now number twenty-seven The president is Dr Madsen of the Danish State Serum Institute The single vice-president hitherto has been M Velghe, formerly secretary-general of the Belgian Ministry of the Interior and Health, but three new vice-presidents have just been elected, one of whom is Dame Janet Campbell of the British Ministry of Health and the others are Dr Heng Liu the Chinese Minister of Health, and Dr Cantacuzene director of the Bucarest Institute of Experimental Medicine In the general body of members Great Britain is represented by Sir George Buchanan, senior medical officer of the Ministry of Health, the United States by Surgeon-General H S Cumming, director-general of the Public Health Service, Canada by Professor J D Fitzgerald, director of the School of Public Health of the University of Toronto and India by General J D Graham, public health commissioner of the Government of India Fourteen other countries are also represented by principal health officials

BENVENUTO CELLINI

BENVENUTO CELLINI'S celebrated autobiography has more than once attracted the attention of medical historians, such as Sir D'Arcy Power and Professor Castiglioni, as it serves to illustrate the close relationship between art and medicine in Italy during the sixteenth century In a handsome quarto entitled "From the Medicine of the Renaissance" [1] Dr Paul Strassmann, extraordinary professor of obstetrics and gynæcology at Berlin University, has recently drawn attention to the passages of medical interest in Goethe's translation of Cellini's life Cellini's medical attendants included Berengario da Carpi, the well-known surgeon of Bologna, and Guido Guidi or Vidus Vidius, the Florentine surgeon and anatomist who has given his name to the Vidian canal and nerve Cellini's own medical history is not without interest There is no doubt that he had several attacks of malaria which was then very prevalent in Rome, and as Signora Celli has recently shown, accounted for the deaths of several Popes He also contracted what was known as brassfounder's ague during his execution of the statue of Perseus at Florence Another febrile attack, accompanied by delirium, from which he suffered for several weeks, may possibly have been typhoid fever On two occasions attempts were made to poison him, once with crushed diamonds without any effect, and on another occasion with arsenic, which nearly cost him his life In spite of the suggestive skin eruption (for which he was treated with guaiacum), and the later eye troubles following Cellini's relations with a model, Dr Strassmann thinks it doubtful if the disease was syphilis in view of the fact that no further symptoms developed and that he became the father of a healthy child in his seventh decennium Like Castiglioni and Vieroidt, Strassmann thinks that there are no grounds for regarding Cellini as guilty of homosexual practices, as some authorities, such as Magnus Hirschfeld, have done

DWINDLING INCIDENCE OF PIRQUET REACTIONS IN SCHOOL CHILDREN

J USTVEDT has investigated, and found to be correct the teaching that the incidence of Pirquet reactions in school children in Norway has shown a remarkable decline during the past fifteen or twenty years [1] In 1914 Arnfinsen carried out Pirquet tests in Trondhjem on 80 per cent of the children attending the primary schools The author has repeated these tests in the same town, checking the reaction after forty-eight hours and regarding as positive a redness or a palpable infiltration at this stage Of the 7 000 school children in the town 4,719 (67 5 per cent) were allowed by the parents to be thus tested The incidence of the positive reactions rose uniformly from 8 per cent at the age of 7 to 40 5 per cent at the school-leaving age of 15 Of all the 4,719 children, 1,116, or 23 5 per cent, gave a positive reaction There was no sex difference between the ages of 7 and 10, but later the incidence of positive reactions was a trifle higher for the boys, and at the age of 15, 43 per cent of the boys and only 37 5 per cent of the girls, showed a positive reaction Arnfinsen's investigations indicated that the frequency of positive reactions rose uniformly from 24 per cent at the age of 7 to 60 5 per cent at the school-leaving age Arnfinsen found 37 8 per cent of all the school children Pirquet positive, whereas Ustvedt reports a reduction in this ratio to 23 5 per cent The difference between the two investigators was greatest in the case of 15-year-old girls, Arnfinsen finding 65 8 per cent to be Pirquet-positive and Ustvedt only 37 5 per cent Since the two series of investigations were conducted with an identical technique and on the same kind of material, it may be safely assumed that during the past fifteen years there has been a considerable postponement in the average date of infection, 20 per cent less of the children pass infected into the dangerous years of adolescence than was the case in 1914 This achievement can probably be traced to the energetic measures taken in the interval to withdraw infectious cases from contact with children There would seem to be no risk in thus deferring the date of infection from the years of childhood to those of adolescence for side by side with an increase in the proportion of Pirquet negative reactions in childhood there has been a diminution of the tuberculosis mortality and morbidity in Trondhjem While in 1914 4 4 per 1,000 of the population of Trondhjem were

[1] *Tidsskr f d Norske Laegeforening*, November 1st, 1930, p 1187

otified as tuberculous this ratio was reduced to 3 5 in 929 The incidence of tuberculous meningitis in children under the age in Trondhjem fell from 3 2 per 1,000 in the eriod 1910-15 to 1 4 per 1 000 in the period 1921-25 In he case of 521 children tuberculosis had been notified n the 371 homes from which they came, but only in 274 f these children (52 5 per cent) exposed to infection as the Pirquet reaction positive Even when the children ame from homes in which a sputum positive case had been notified as great a proportion as 31 per cent of them ere Pirquet-negative Sometimes, when there were two or more children in one and the same tuberculous family son e of the children were Pirquet-positive and other Pirquet ne ative The author compares this state of affair with the observation that even artificial inoculation with B C C does not invariably provoke a positive Pirquet reaction The sub equent fate of children living in tuberculous surroundin s does not seem to be affected by the nature of their Pirquet reaction at any given date for of the 444 children from tuberculous surroundings examined by Arnfinsen in 1914 37 5 gave a ne ative reaction Of these 167 children, 13 or 7 8 per cent were subsequently notified as suffering from tuberculo is Of the 277 giving a positive reaction in 1914, 22 or 7 9 per cent , were sub equently notified as tuberculous

ORIGIN OF THE HUMAN SKELETON

DR ROBERT BROOM although trained as a medical man has spent the greater part of his profe ional life in studying the fos il fauna of South Africa The fauna is a very ancient one, its fossil remains are dug from rocks of the Permian Triassic and Jurassic Ages and pre erve evolutionary stages which preceded the appearance of the true mammals The highest vertebrates were then reptilian in type, but many of the reptilian forms of South Africa were undergoing changes which heralded the dawn of the mammalian type Certain modifications of structure were bein effected which have still an interest for medical men In diverse genera the mammalian form of palate was being evolved—forming a roof for the mouth and a floor for the nasal cavity In every human child this same process occurs during development failure gives ri e to "cleft palate" Another marvellous change was the establishment on the base of the skull of a new joint for the lower jaw Dr Broom has succeeded in finding only the preliminary steps which led on to the separation of the old articular head of the lower jaw to form the hammer of the ear and the outgrowth of bone to form a new mandibular condyle In the present study[1] the lore gained in the examination of this ancient fauna has been applied to elucidate the human skull and skeleton Although a period of 200 millions of years—the estimate is Dr Broom s—has elapsed since these mammalian like reptiles had their day in South Africa yet much of what was theirs has been handed on and become the heritage of man and ape The student of anatomy may be con oled by the knowledge that the human skull is much impler in its structure than was the highe t form of kull in the Triassic period Eight bones which were separate in the ancient Theromorphs have been enrolled in the human sphenoid bone their orbit had in its circuit six separate bones, compared with that of man s Theromorphic ancestor the human bony palate is a simple structure Even in the earliest reptilian forms however the tarsus and carpus had much the same constitution as till persists in the hand and foot of man Dr Broom has an interesting and original story to tell and makes it o intelligible by the aid of simple drawings that a first-year medical student should find no difficulty in following all the details of his argument

PUBLIC ASSISTANCE ORGANIZATION

IT is very de irable that knowledge of the new machinery which ha super eded that of the old boards of guardians for the admini tration of the Poor Law should be as wide pread a po ible In the large area of the London County Council this new machinery ha been the subject of much careful thou ht and it is now in e tabli hed working and of course affects a relatively large proportion of the total population which is in need of public a istance A small pamphlet entitled *The New Public Assistance Organi ation of the London County Council*[1] by Lewis Silkin a member of that Council is therefore timely in its publication and worthy of attention It has a foreword by the Right Hon George Lan bury M P First Comm issioner of Work and is publi hed under the au pices of the London Labour Party It is not therefore wholly free from party bias but an attempt i made in the main succe sfully to avoid the di cu ion of question of policy, and to restrict the pamphlet to giving the reader sufficient information to enable him to appreciate the effects of the important chan e which has now taken place in the administration of public assistance within the County of London Many medical practitioner both in London and elsewhere should appreciate an exposition so brief and so clear as that which this pamphlet afford It sets out in an admirable manner the extent and nature of the work done under the old re ime and the way in which it is being consolidated and redistributed under the authority of the London County Council A few concluding paragraphs contain observations of a more general character as to the effect and intentions of the new admini tration and one or two of these may be of special significance It is known that the Labour party is generally not in favour of co-option on to the committees of local government authorities There are strong ground for concluding that this is a mistaken attitude In view of the extent variety, and complexity of the problems with which such authorities have to deal it eems clearly advantageous to enli t to a modest extent in committee work those who have expert knowledge experience and kill in particular spheres but who do not wi h to plunge into public work of a wider character In Mr Silkin s pamphlet it is acknowledged that provided such persons are carefully selected and are prepared in addition to making a sacrifice of their time to undergo the education and training whi h i e sential for all persons who desire to take part in public life, then the advent of an increased number of presumably public-spirited per ons in the civic life of London can hardly be without its advantages ' It is bad election which i probably at the bottom of such real di i faction as at present exists Where the prime consideration i either narrow party advanta e or question of mere relationship or friendship failure may easily re ult, but there can rarely be any county or county borough in which there is not sufficient election from those who not only have the requisite knowledge and experience but al o have actually had in ome form that training in public life which Mr Silkin very properly postulates as neces ary Again it is said persons seeking assi tance who are admittedly too old for work and without means of ub i tence ' ould be provided with as i tance out ide the Poor Law altogether and it po ible through a committee of the Coun il pecially et up for the purpose It i common ground that the ultimate goal i the breaking up of the Poor Law o that those who need public a si tance on special groun ds shall be dealt with appropriately but surely the cla named are exactly those for whom the public a istance committee should be most concerned and who hould be its foremo t consideration

CONFERENCE ON MENTAL WELFARE.

A very largely attended conference was held, under the auspices of the Central Association for Mental Welfare, in the Great Hall of the British Medical Association House, Tavistock Square, on December 11th, 12th, and 13th. It was opened by the Right Hon. ARTHUR GREENWOOD, the Minister of Health, who expressed the hope that voluntary associations would do much useful work in the administration of the Mental Treatment Act. Without the completest harmony between the State, the local agencies, the medical profession and the voluntary associations, administration could never be effective. The Right Hon. SIR LESLIE SCOTT, president of the convening association, described the Mental Treatment Act as the most important step forward in the establishment of a preventive mental health service in this country, and indicated its three great salutary provisions: out-patient clinics, the provision of beds for temporary patients in general hospitals, and the admission of voluntary patients to mental hospitals. The first of these provisions would bring for the layman, and he hoped for the general practitioner as well, the treatment of mental illness into the same category as the treatment of physical illness.

Problems under the Mental Treatment Act

The first subject for discussion at the conference, under the chairmanship of SIR LESLIE SCOTT, concerned the developments in mental health work under the Mental Treatment Act 1930. It was opened with two papers, the first by SIR WILLIAM HART, town clerk, Sheffield, who, in the course of his remarks, urged some considerations of economy. The constant demand for expenditure upon new or extended social services, coupled with stringent times as regards finance made it very difficult for local authorities to contemplate expenditure on a large scale on such matters as new institutions. While everything would be done to secure the fullest provision of opportunities for preventive treatment, and to further in all respects the aims embodied in the Act, many of those concerned were not compelled by reasons of finance to ask that progress might be slow because of financial stringency. The second paper was by DR. A. T. W. FORRESTER, medical superintendent Warwick County Mental Hospital, who discussed the development of out-patient clinics. He gave reasons why the mental hospital staff must, in his opinion, be associated with the clinic. The treatment of mental disorders in this country was in the hands of quite a small number of medical men, most of whom were on the staffs of the public mental hospitals. Outside the hospital, at the clinic they would see chiefly the same patients but in the earliest stage of their disorder, and this was the stage at which those who were largely concerned with the mental health of the community wished for the opportunity of beginning treatment. Surely, also, it was highly desirable that there should be continuity of treatment between the out-patient clinic and the admission hospital, and to ensure this it was vital that the staffs of the two units should be closely interrelated, if not identical. As to the three possibilities for the site of the clinic—namely, the general hospital the municipal hospital, and the mental hospital he thought there was only one answer—namely, that the general hospital was the most preferable site. The clinic would also form a very useful centre where discharges from the mental hospital could report from time to time.

DR. J. R. FOTHERGILL urged strongly that the treatment of mental illness should be brought into line with the treatment of all physical illness, and that if the service was to be a successful one, just as in the case of physical illness, the treatment of mental illness should be founded on the general practitioner, the private consultant, and the medical officer of the mental hospital. Admission to the consultation department of a voluntary hospital should be through the general practitioner, to whom a report should be sent, with a recommendation as to the form of treatment if the patient was not considered suitable for admission. There was a question whether the whole-time medical officer—that is, the superintendent of the mental hospital—was the most suitable person to be in charge of the consultation department. The knowledge of such an officer concerned rather the end-results of illness and not at present its commencement. It should be kept in mind that if a whole-time superintendent of a mental hospital were appointed as medical officer of the consultation department, where he gave his services free, he would be at once in competition with the private consultant in that branch of medicine, and the latter would be deprived of the means of keeping his education up to date, and of the remuneration which he had a right to expect to receive from the hospital, whether voluntary or council.

The Staffing of Out-patient Clinics

MR. L. G. BROCK (Chairman of the Board of Control) referring to the two questions which had come up in the course of the discussion—namely, as to where the out-patient clinic should be and where the admission hospital should be—said he was inclined to agree with one speaker that the superintendents of mental hospitals were too modest about their own claims. It must be recognized that outside a few of the largest urban areas and the areas of the large voluntary hospitals with neurological wards, there were really not in this country any men, other than the members of the staffs of mental hospitals, with any considerable experience in psychological medicine or in dealing with cases of mental disorder. Whatever improvements there might have been in the medical curriculum in recent years, the medical student had lamentably little opportunity of studying cases of mental disorder. It was to the staffs of the mental hospitals that one must look to find the men who had made a special study of this work, they were the experts, and he could not see why the fact should not be admitted. That was why he wanted to see the superintendents and staffs of the mental hospitals associated with the out-patient clinics. But while it seemed essential to the success of the out-patient clinic that it should be staffed in the main by men who came from the public mental hospitals, at the same time he was very anxious to break down the barrier which had existed in the past between psychological and general medicine. He wanted to see the out-patient clinic staffed by the medical superintendent and his assistants, but he wanted to see it at the voluntary hospital, and, in return, to see the consultants of the voluntary hospitals becoming the consultants of the mental hospitals. The more interchange that could be got between the two the better. One great reason why the out-patient clinic should be at the voluntary hospital was because the condition precedent to any success was to secure the confidence of the patient, and he was sure it was easier to get him to go to a voluntary hospital at the earliest stage of his malady than it would be to get him to go to a mental hospital. It was also well to bear in mind that the people concerned were suffering not only from mental illness but in a great many cases from physical illness also, and, however well equipped the mental hospital might be, there must be better resources in the voluntary hospital for dealing with ordinary sickness. He totally disagreed with one speaker, however, who had stated that the voluntary hospital was the proper place in which to have the admission unit. The voluntary hospital might well be the best place for certain borderline cases which should go to the neurological ward and for certain cases complicated by physical symptoms, but the great majority of admission cases should be handled in the mental hospital itself.

DR. THOMAS BEATON (medical superintendent, Portsmouth Mental Hospital) said that there was no reason why the out-patient clinic should not be worked in the closest co-operation with the general practitioner. His experience had been that general practitioners were only too ready and anxious to get opinions on their cases, and he could assure any general practitioner that he would not suffer in the slightest degree from the advent of the clinic. There was no reason why the general practitioner should not follow up his cases, and he wished that he would take a little more interest in his patients after their admission to the mental hospital. The difficulty was to get the general practitioner to come. It had been said that medical superintendents of mental hospitals were quite

unfitted to tackle the difficult problem of mental deficiency. This he strongly controverted. The medical superintendent had constantly to deal with the problem of abnormal conduct and he saw very grave danger in separating the two branches of the work, the one relating to mental deficiency and the other to lunacy. Both required the same type of investigation, and although the cases needed different handling afterwards they had to be differentiated and sorted out in the first place.

In some further discussion Dr. CORSTON WILLIAMS pointed out that there was a large class of the community who were suffering from a sick mind, which was neither a disease for the asylum nor a manifestation of mental defect. He welcomed Dr. Fothergill's suggestion that there should be developed within the medical profession people who had a knowledge of psychiatry for dealing with these cases.

Causation and Prevention of Mental Deficiency.

The subject for discussion on the second afternoon of the conference was "The need for an inquiry into the causation and prevention of mental deficiency." Sir BASIL BLACKETT occupied the chair.

Dr. R. LANGDON DOWN, in introducing the subject, said that from certain points of view a Government inquiry might be the best form of machinery for arriving at more exact knowledge of the nature and causation of the various types of mental deficiency and of the operation of heredity in relation thereto; but such an inquiry had some drawbacks as a scientific instrument and was apt to be inconclusive by reason of the tendency to temper truth with policy. The request for a Government inquiry had been associated with the proposition that all legislative measures in regard to sterilization should be postponed until the findings of the inquiry were issued. If it were intended to pass into law a policy of compulsory wide spread sterilization forthwith such an attitude might be justified; but what was now proposed by the Eugenics Society was that it should be made lawful for medical practitioners to carry out simple sterilizing operations with the consent of the person or, in certain cases with the consent of his or her parents or guardians, but only under such safeguards as might be necessary to prevent the improper use of such methods. Such a proposal did not involve the assertion that there was no need for further inquiry on the contrary, if adopted without unreasonable delay it might provide the inquiring body with evidence about the procedure which so far as this country was concerned was not available at present. He maintained that the recent inquiry by the Wood Committee justified a cautious and tentative move forward on the lines suggested by the facts which the Wood Report had brought forward. The Wood Report stated: "If it could be proved that sterilization could be safely and profitably applied even to certain groups of categories of defectives the question of its adoption would no doubt deserve attention. But obviously such proof could only be obtained as the result of trial and yet the trial could not be made until the procedure was sanctioned by law." He held that arguments pointed strongly to the transmissible nature of the condition and to its origin in heredity rather than in environment. As for segregation, this could only be applied to one-third of all certifiable defectives, and he urged sterilization not as a substitute for, but as a supplement to, segregation.

Dr. C. P. BLACKER, supporting the proposition advanced by Dr. Langdon Down, said that people were apt to approach the question of causation with certain preconceived opinions. People holding Labour sympathies were extremely reluctant to admit that any form of social inferiority could be due to intrinsic causes; they regarded all such inferiority as the product of environment. The other extreme was taken by people who believed strongly in inheritance and the potency of innate characters; these were people who themselves came of distinguished families and of whose record the individual was proud. Between these two extremes came the bulk of public opinion. The question of prevention was a more thorny one, and he believed that in a short time there would be a very intensive campaign against sterilization conducted by sincere and able leaders of the Roman Catholic Church. Any committee or commission would necessarily have to go into great detail, and its inquiry would take a long time. Meanwhile he would point out that the means of prevention suggested by the Mental Deficiency Committee—namely, segregation and prohibition of marriage—were inapplicable to what might be called the social problem group, and that the only method at present available for limiting the fertility of that group was sterilization. Sterilization might prove to be a remedial measure not only for primary amentia, but also for secondary amentia due to injury before birth, owing to attempts at abortion or to injury at birth or in early infancy. What the Eugenics Society proposed was that eugenic sterilization under proper safeguard should be at once legalized. He thought the safeguards would be quite sufficient seeing that the Board of Control would never give its consent to the sterilization of a defective unless there were excellent reasons for doing so. So long as that sanction held good he thought that abuses would be non-existent. He added that the Eugenics Society had prepared a bill on the subject.

The Case against Sterilization.

Dr. A. F. TREDGOLD, who spoke in opposition to what he described as "this plausible remedy," said that it was not without interest to consider that the demand was no longer for the wholesale sterilization of all defectives; it was simply to be an experimental measure for a selected group. What was sterilization going to do toward the prevention or lessening of mental defect? The general public were under the impression that if only sterilization were adopted mental deficiency would be eliminated, and the Eugenics Society made the definite claim that if all mental defectives were prevented from having children the number of defectives in the country would be halved in about three generations. But his impression as the result of many years' experience was that the number of mental defectives who were the offspring of defective parents was a very small proportion of the whole, probably not more than 5 per cent. That percentage represented the extent to which the number of defectives would have been lessened had all defectives been sterilized a generation ago. He protested against the way in which the public were being misled on this matter. There were certain definite difficulties and risks in sterilization which he did not think the community was justified in running especially in view of the negligible benefit which would result. He indicated the difficulty which would arise in the selection of cases, and also the likelihood if sterilization were practised of increased promiscuous sexual intercourse. Further he submitted that if the sterilization of defectives were legalized there would be a real danger of delaying the true solution of the problem. The public would consider the matter disposed of, and be content to wait for results which would never come.

Dr. F. C. SHRUBSALL, after remarking on the difficulty of ascertaining any exact statistics, ventured the statement that in 75 per cent. of defectives of the lowest grade the condition might be said to be secondary amentia—that is to say, from causes arising from some accident since conception. In the slightly higher grade—the imbecile—about 45 per cent. were due to secondary amentia. With regard to the feeble-minded no figure could be given on present records, but it could be stated with certainty that more than 10 per cent. of these were cases of secondary amentia. About 9 per cent. of defective individuals had defective brothers or sisters, and the majority of these cases were of simple primary amentia. If it were possible to acquire a knowledge of the full family history of a great number of cases, including the grandparents and the collateral branches, a great deal more would be learned about the methods of inheritance and distribution. It had to be remembered that there were many examples of feeble-minded persons from the educational standpoint who from the biological standpoint merely represented a lower grade of culture. The most dangerous type of case to deal with was the very high grade defective, and the higher the grade the greater the prospect of parenthood. But of course the higher the grade of case the more difficult it would be to conduct an examination if an idea got abroad that consequent on being deemed a defective, the person might be sterilized. The difficulties of the certifying officer

would be greatly increased by any precipitate action with regard to sterilization

DR F DOUGLAS TURNER said that one of the gaps in genetics was the absence of knowledge with regard to the causation of mental deficiency It was impossible to think that the hotchpotch of diseases and conditions described as mental deficiency could be inherited along one single line or be due to any one cause In Denmark, where some careful statistics had been worked out, it was stated that among the lower grades of mental defect 80 per cent were due to secondary—that is, preventable—causes Some years ago he went carefully through his own case papers and made inquiry into the families of those in his institution, and found that, going back in the direct line, only 2¹ per cent in each generation had had defective parents or grandparents He also remarked on the very small proportion of such persons whom it was considered necessary to retain in an institution for fear that if living in the community, they might have children, in some figures of his own, relating to 1,300 patients, this proportion was from 1 to 1½ per cent of males and 1 per cent of females

DR H B BRACKENBURY thought that some suitable departmental commission or committee might well be appointed, though such a body was not a very appropriate instrument of research He would not expect it to embark upon experimental research, but it could cover a very wide field of information and set it forth in an authoritative manner The advance of knowledge on this subject had been considerable, and it was difficult for any individual to keep up with it They were all in danger of remaining in a state which would have been an advanced state of knowledge eight or ten years ago What were the sort of questions into which such a body might inquire? One question was as to the common level of general intelligence of the people of this country to-day He thought they were all inclined to place it too high On the answer to the question depended to a large extent the definition of mental deficiency Further, how far was it true that feeble-minded parents tended to have families larger than the average size? It was a legend that they had such families, but there was little foundation for it after all The latest results definitely indicated that the number of children who arrived at adolescence in a family the parents of which were themselves mentally deficient was scarcely higher than the average number in the general population He also believed that the latest investigations of the results of placing these people in suitable environment outside institutions under proper supervision proved that, when in the community, they behaved themselves both socially and sexually in as decent a manner at least as the rest of the population That was another point for inquiry The speeches made that afternoon had caused him to recede somewhat from the position that there was room at the moment for a legislative measure allowing sterilization He was not at all sure that it would be a wise thing even to take the preliminary step advocated by Dr Langdon-Down Dr Langdon-Down had assumed that there would be such an amount of sterilization taking place in consequence of that measure as to allow important conclusions to be drawn therefrom If it was to be as widespread as that, he was not sure that these tentative proposals ought to be supported

One or two members of the general audience addressed the conference briefly, including one Catholic priest, who said that the Roman Catholic Church would resolutely oppose by every means in its power such a measure as had been suggested The only method it could sanction was segregation

DR BRACKEN briefly replied, there was no resolution, and the CHAIRMAN, in closing the meeting, said that, diverse as were the opinions which had been expressed, everyone seemed to agree as to the need for an inquiry

The Voluntary Worker

Social services in connexion with mental hospitals were also the subject of debate at the conference MR L G BROCK remarked that much of the success of the out-patient clinic would depend upon the choice of the right kind of social worker An unpaid voluntary worker might be more acceptable to the patient than the highly trained expert At the bottom of the British preference for the amateur as against the expert was a sound instinct, for in the end sympathy and other personal qualities might count for more than mere efficiency or right technique DR THOMAS BEATON spoke to the same effect His insistence that the ideal social worker should know nothing about psychology caused some surprise and amusement

An interesting paper was read to the conference by DR E O LEWIS (Inspector, Board of Control) on the ascertainment and notification of mental defectives, especially retarded children, at present the most neglected group in the educational system Several directors of education discussed the problem of school reorganization from this point of view

On the first day of the conference the delegates were received by SIR LESLIE SCOTT at a luncheon at the Hotel Russell, when the guest of honour was MR L G BROCK chairman of the Board of Control, in place of Lord Riddell who was unable to attend on account of illness MR BROCK remarked that the service in which he and his colleagues were engaged was an unpopular health service, almost the only health service which was generally unpopular But the Board of Control certainly derived great help and encouragement in facing public opinion from the support which they received from the Central Association for Mental Welfare and from the local voluntary associations No central authority, whether the Board of Control or the Ministry of Health, could ever go far in advance of public opinion, and he confessed that there were times when he felt that the problem of dealing with mental deficiency would be insoluble were it not for the encouragement received and the lessons learned from the faith, devotion, and single-minded enthusiasm of many of those who worked in the voluntary associations up and down the country

Nova et Vetera.

THE DOCTOR LOOKS AT REMBRANDT

IN the series of "Great Painters and their Works, as Seen by a Doctor," keeps up to the standard of Dr J G De Lint's *Rembrandt*[1] it should be a source of great interest and pleasure to many of our readers The purpose of the series of monographs, DR DE LINT tells us in his preface, is "to analyse the works of the Dutch painters of the seventeenth and eighteenth centuries and to notice what they contain of medical interest" Time only will show whether other painters can be made as medically interesting as Rembrandt, whose works present a surprising wealth of subjects connected with medicine and surgery, some represented by etchings and others by oil paintings, such as the celebrated "Lecture on Anatomy," now in the Mauritshuis at The Hague

Public dissections seem to have been popular entertainments in the sixteenth and seventeenth centuries, and other artists besides Rembrandt took them for subjects of paintings and engravings and etchings Some of these are reproduced by DR DE LINT, but none of them can compete with the "Lecture on Anatomy" of Nicholas Tulp, painted in 1632, which, by the way, was evidently meant for a serious demonstration to professional men, whose portraits are included in the picture and whose names are on record We even know the name of the corpse and the fact that he suffered death for "wantonness" The demonstrator, Nicholas Tulp, took his name and arms from a tulip carved in stone on the house in which he lived He was a celebrated anatomist in his day, and a leading citizen who became Burgomaster of Amsterdam His son-in-law, Arnoult Tholinx, was also an anatomist, and had his portrait engraved by Rembrandt In no other European country was science held in such esteem or its teachers so honoured as in Holland in the sixteenth and seventeenth centuries In the latter period Boerhaave was the most

[1] *Rembrandt* By Dr J G De Lint Great Painters and their Works, as Seen by a Doctor I The Hague J P Kruseman 1930 (6½ × 9½, pp 113, 64 figures 10s)

celebrated and honoured man in the Low Countries, and there was nothing exceptional in an anatomist becoming a burgomaster in those less enlightening days. Excellently as Sir Arthur Keith would fill the office of Lord Mayor of London, or Professor Elliot Smith that of chairman of the London County Council, neither of them could nowadays be spared from their important archaeological and anthropological researche

It is rather surprising to learn that in the matter of human anatomy Holland was chronologically behind Scotland. As mentioned in a Novi et Vetera article in these pages,[1] the town council of Edinburgh ordered the body of "ane condampnit man" to be handed over to the Company of Surgeons for dissection as early as 1505, thirty-eight years before the publication of the great work of Vesalius. The earliest recorded public dissection in Holland, according to Dr. De Lint, took place in Amsterdam in 1550, and in 1555 Philip King of Spain and Count of Holland gave a privilege to the Corporation of Surgeons of that city to have the corpse of a criminal once a year for their instruction. Rembrandt's picture is justly the most celebrated, but it is by no means the earliest representation of a dissection in Holland. Petrus Paauw or Pauius, founded an anatomical theatre in 1592 at Leyden, and dissected sixty bodies in twenty-three years. The public regarded the dissections as a kind of show, and were admitted to the third row of the amphitheatre on payment. W. P. Buytenwech made a sepia drawing of Paauw's lecture before 1627, and Andreas Stockius engraved it from an opposite point of view. Dr. De Lint says that the portraits of several well-known people of the time can be recognized among the many visitors. Michael and Peter van Mierevelt's "Lecture on Anatomy," containing the portrait of Dr. van der Meer and seventeen visitors, was painted in 1617. Dr. De Lint does not tell us, however, where this picture now is. Rembrandt painted another lecture on anatomy by Dr. J. Deymann, but it was nearly destroyed by fire in 1723, and only a sketch in the Six Collection remains to show its composition. Besides the dead body and the lecturer, it contained the portraits of eight physicians. In paintings and etchings Rembrandt has left us various portraits of physicians such as Ephraim Bonus, Jan Antonides van den Linden, and Arnoult Tholinx, which are reproduced in this book.

The Parable of the Good Samaritan was a subject which evidently interested Rembrandt. He represented various scenes from it in his etchings and pen-and-ink drawings, of which no fewer than six are reproduced in this book, as also the Circumcision of Christ, which was treated by the artist in numerous works, one of which, an etching, is reproduced by Dr. De Lint. The story of Tobit's blindness, due to sparrows dung, and its cure by the application of the gall of a particular fish by his son Tobias, is a curious piece of folklore and, mixed up as it is with another typical story of the virgin whose embrace was fatal to seven men in succession, as told in the Apocrypha, it furnished matter for a number of works by Rembrandt. As Dr. De Lint notes, it is curious that in many of the representations of persons wearing glasses these seem to have no side-pieces, as do regular spectacles, but apparently are eye-glasses and worn low down on the nose. In the portrait of Arnoult Tholinx such glasses are clearly shown held between finger and thumb. This is one of Rembrandt's rarest etchings.

Other more or less medical subjects illustrated by the master were internal medicine, miraculous healings, surgery, and the *lying-in room and care of infants*. It would be impossible in a notice such as this to do justice to them as treated by Dr. De Lint. Readers who wish to see these excellent reproductions of sixty-four pictures are recommended to get the volume, which is decidedly cheap at ten shillings. We presume that the author has put his work into English himself. If so, it shows a very good knowledge of the language. Only one amendment occurs to us—namely, that *dissect* and *dissection* should be substituted for *prepare* and *preparation*, which words are not used in the same sense in England as on the Continent.

France.

[FROM OUR OWN CORRESPONDENT]

Congresses in Paris.

Autumn brings back to Paris both physicians and patients, so we are told. The Faculty of Medicine opens first for the benefit of that special type of student—the senior practitioners. They meet in various congresses. The Thirty-ninth Congress of Surgery was opened by the celebrated novel-writer Paul Bourget, who is well known for the interest he has always taken in medicine. The president, Dr. Auvray, insisted on the need for training anaesthetists up to a high standard of specialization, following the example set by Great Britain and America. By the way, it seems rather extraordinary that such a move should still have to be considered. Drs. Lambret and Sauve discussed pre-operative treatment and the necessity for methodical study of functional tone. Professor Archibald Young of Glasgow laid stress on acidosis, renal elimination, and the psychological factors in anaesthesia. The second question debated was that of traumatic spondylitis. Next year the congress will discuss the three following questions: post-operative peptic ulcers, immediate surgical treatment of compound fractures of the leg, and pneumococcal pneumonias. Among other congresses that met in Paris last month may be mentioned the First Congress of Aesthetic Surgery. I have already alluded to the difficulty this specialty has had to deal with in the law courts. It seems to have been considered by the judge as a *de luxe* surgery, not worth while the dangers that must be involved necessarily in every surgical operation. But the social importance of the question has been emphasized. If it is true, as Pascal puts it, that the whole face of the world would have been different if Queen Cleopatra had been endowed with a turned-up nose, it is just as true to say that many have seen their career ruined nowadays because their profile is very far from the Cleopatra standard. Such a handicap may be, and should be, corrected. The First International Congress of Orthopaedics was held under the chairmanship of Sir Robert Jones of Liverpool, who delivered the opening address, entitled, 'The surgery of motion." Two questions were discussed—namely, the treatment of congenital dislocation of the hip after the fifteenth year, and the treatment of traumatism of the wrist. The Thirtieth Congress of the French Urological Association discussed kidney contusions, and the prize of the association was awarded to Dr. Chabannier, well known for his pioneer work in the field of urology. At the Pasteur Institute was held the Seventeenth Congress of Hygiene and Public Health. Infant mortality was discussed in connexion with B.C.G. vaccination. The method is extensively employed in France, with gratifying results.

Efficacy of Antidiphtheria Serum.

The Academie de Medecine has been asked by the Secretary of the Ministry of Public Health to investigate the efficacy of antidiphtheria serum as it is now handed to the practitioner. Some have contended that they had to use larger doses than formerly in order to produce similar effects. A queer explanation was suggested for such a fact. The bacilli had spontaneously increased their virulence in order to overcome the protective action of the serum! It is true that since 1925 the serum has been prepared by injecting the horse with anatoxin and no more with the toxin. This increases the strength of the serum to 325 antitoxic units per cubic centimetre, as compared with the 250 which were obtained formerly. Professor Renault, who reported to the Academie, laid special stress on what used to be called "Le Genie Epidemique." Mortality seems to have varied during successive epidemics from 13 to 85 per cent. During the last nineteen years his statistics show that mortality in serum-treated cases reaches 50 per cent. between the ages of 7 and 12 months, 40 per cent. between 1 and 2 years of age, 17 per cent. from 2 to 3, 13 per cent. from 4 to 5, 8 per cent. from 5 to 10. After the age of 10 the death rate is almost *nil*. As regards the value of the serum as it is now delivered his conclusions are optimistic.

Death of Dr Auclair

Dr Auclair died a few weeks ago For twenty years he had been carrying out, in Paris hospitals, original research on vaccination for tuberculosis He reported his results at the Academie de Medecine on February 1st, 1930, and in a book just issued Studying the infection in animals, he came to the conclusion that it was more a question of soil than a question of germ Why, he asked, are birds immune against the human bacillus? Dr Auclair proved experimentally in hens that it was due to some pancreatic secretion Taking a mixture of pancreatic extract with Koch's bacilli, he injected this into rabbits and guinea-pigs, and successfully immunized them against human tuberculosis The immunizing substance which existed in the pancreas of the hen had been activated in the extracts It became fixed when in contact with the bacilli, and the combination acted as a vaccine Such a vaccine stimulated the pancreas of the rabbit, a new secretion started, which was able to check and to destroy the bacillus Dr Auclair died before he could complete a demonstration which the world was waiting for, but his investigations on human beings led him to think that his vaccine had both a preventive and a curative effect The experimental stage of his work has been carried very far indeed Let us hope the question of dosage and of repeated injections will now be studied

G MONOD

Ireland.

Diphtheria in Dublin.

AT a meeting of the Section of Pathology of the Royal Academy of Medicine in Ireland, held on November 28th, with Dr J Lait in the chair, Dr R A Q O'Meara read a communication entitled "The prevalence of diphtheria carriers among Dublin school children" In all he had examined 1,000 school children between the ages of 3 and 13, and had taken nose and throat swabs from each Morphological diphtheria bacilli were present in swabs from fifty of the children From 82 per cent of the carriers the organisms were isolated and subjected to fermentation and virulence tests The results showed that 5 per cent of the children were carriers of virulent and non-virulent, while 2 3 per cent were carriers of virulent, diphtheria bacilli He estimated that there were some 3,000 carriers of diphtheria bacilli in the Dublin schools, of whom 1,400 were carriers of virulent organisms The carrier rate was higher for girls than for boys The virulent bacillus carrier rates for the north side of the city, the south side of the city, and for the whole city were the same—namely, 2 3 per cent The importance of nasal swabs in searching for carriers was emphasized by the fact that 25 per cent of the positives were nasal carriers only, 18 per cent were throat carriers only, while 7 per cent were carriers in both nose and throat The organisms were virulent in 44 per cent of the nasal carriers, in 43 per cent of the throat carriers, and in 68 per cent of the nose and throat carriers Dr W R O'Farrell said that he had done some work on similar lines to that described, and referred to the importance of the intermittency of the carrier state and its bearing on the results obtained in any locality Dr M J Russell, medical officer of health, said that the schools of the city were overcrowded and, enhancing as they did the opportunities of spreading infection, the carriers were a grave menace The public health authorities, to overcome this menace and to prevent the disease as far as possible, had adopted prophylactic inoculation of children before school age A clinic had been established for that purpose, and was actively engaged in the administration of toxoid-antitoxin mixture In this way it was hoped that the incidence and mortality of the disease, which had shown a distinct upward tendency in recent years, would be lessened He appealed to doctors to isolate promptly all cases and to delay discharging convalescents until they no longer harboured the diphtheria bacillus No doubt overcrowding, lack of light and air, and defective food assisted in causing the disease Dr W F Cooper suggested that the inculcation of cleanly habits into the poorer children in Dublin schools would help in reducing the number of carriers Dr O'Meara, in reply, said that he did not recommend the Schick test as a method of distinguishing the carrier from the early case The distinction could best be made on clinical grounds, and in cases of doubt serum should be given The intermittency of carriers was well recognized, and in addition the number found in an investigation depended upon the technique adopted in searching for them If the technique were standardized, and a large enough number of children were examined, he believed that a significant average for comparative purposes could be obtained The difference between virulent and non-virulent diphtheria bacilli was that the former were toxin-producing, whereas the latter were not The non-virulent type was harmless and did not give rise to the virulent type There was no necessity for antitoxin when only non-virulent organisms were present

Dissolution of the County Galway Board of Health

Owing to the repeated refusal of the Galway Board of Health to appoint an assistant medical officer of health, as requested by the Department of Local Government and Public Health, the Minister has caused a letter to be addressed to the board, in which he refers to his obligations under Section 72 of the Local Government Act, 1925 For some considerable period, he states he has had grave doubts of the capacity and efficiency of the Galway Board of Health He draws attention to its protracted delay in providing suitable hospital facilities at Clifden and Ballinasloe, although many representations were addressed to it on the subject He notes that on March 26th it committed itself to a policy of abrogating its authority as regards disciplinary questions affecting dispensary medical officers The Minister considers that the conduct of the board in these instances is bound to react unfavourably on the interests of the sick poor throughout the county, and seriously affect the efficient administration of the Poor Relief and Medical Charities Acts by undermining disciplinary authority Commenting on the apparent opposition of the board to the reorganization of public health services, the Minister refers to the recent inquiry—described in the *Journal* of December 6th (p 976)—which indicated that the board, in spite of repeated warnings by the department, had obstructed the carrying out of the duties of the county medical officer of health by declining to appoint an assistant officer to act as tuberculosis officer and school medical officer In consequence, the county tuberculosis scheme had partially fallen into abeyance since September 30th, with unfavourable results to patients who had been under treatment Moreover, after consenting to appoint two public health nurses, and when the procedure for their selection was already well advanced, the board had rescinded its decision and refused to proceed further with the matter In these circumstances, the letter concludes, the Minister sees no other course in the public interest but to exercise his authority under the section of the Act referred to, and has accordingly issued an Order under Seal, dissolving the Galway Board of Health and Public Assistance, and transferring its powers and duties to Mr E S MacGuaigin of Belmont Villa, Cavan

Damages Against Medical Officer of Health

Damages were claimed at Roscommon by Michael Campbell and Mrs Brennan, Four-Mile-House, against the County Roscommon Board of Health and Dr Maguire, county medical officer of health, for clothes and other articles burned in a case of infectious fever It was stated that following the death of one occupant of the house, and the removal of another to hospital suffering from typhus, Dr Maguire, who had been called in, decided that the inmates and contents of the house should be disinfected, and arrangements were made at the County Home to have this done Patrick Campbell appealed to Dr Maguire not to have the clothes and bedding taken to be disinfected, on the ground that the publication of the fact that there was fever in the family would be injurious to their business He subsequently signed a document

indemnifying Dr Maguire against any action or claim if he should decide to have the articles burned After considerable pressure Dr Maguire agreed, and the clothing and bedding were burned Following a refusal by the Board of Health to compensate the plaintiffs they issued civil bills against the board and Dr Maguire claiming over £200 damages They denied that Patrick Campbell had any authority from them to have their property destroyed For the defence it was urged that Dr Maguire was merely carrying out his duty under the Act and that he believed that Patrick Campbell had full authority to act for the family Judge Moonan dismissed the case against the board and gave decrees against Dr Maguire for £90 and £75 respectively He expressed the hope that the board would not allow Dr Maguire to suffer any loss in the matter

England and Wales.

King Edward's Hospital Fund for London.

THE annual distribution meeting of King Edward's Hospital Fund for London was held on December 12th, with the Prince of Wales in the chair A letter was read from the King expressing his satisfaction that the distribution to the various hospitals had increased from £250 000 to £266 000, and that £16,000 had also been received on capital account The Prince of Wales in his speech, explained that the increased distribution had been rendered possible by a donation of £10,000 from an anonymous friend, who had now contributed during the past few years a total of £54,000 Moreover, there had been considerable additions to the capital fund, the income from which was the solid foundation for these annual distributions In addition to the £266,000 distributed, pension grants of £16 468 had been made A further 6 grams of radium had been purchased, a deficit of £8,000 having been met in advance by the late Sir Otto Beit just before his death The annual grant to convalescent homes had been increased from £2,000 to £3,000 Lord Marshall reported that the League of Mercy had been able to allocate from the King's Fund a sum of £17,000 from its collection The number of hospitals receiving grants this year was 141 as compared with 143 last year No reduction had been necessary in the general scale previously adopted and the additional money obtained has enabled certain hospitals which were in exceptional difficulties to receive special assistance The total of the present distribution taking into account grants for ordinary maintenance for capital expenditure, and for special pensions was £279 468

Old Epsomian Dinner

'Floreat Epsomia, Floreat, florebit," says the chorus of the *Canticum Epsomiense* The enthusiasm of the company of 150 old boys and guests, and the speeches of the president and the head master at the fifty-third annual meeting and dinner of the Old Epsomian Club held on December 11th at the Wharncliffe Rooms proved abundantly that the College is flourishing and will continue to flourish Mr A C C Parkinson, in characteristic fashion proposed the toast of the president, Dr L L C Reynolds He said it was typical of Dr Reynolds throughout his life that he never let himself or his men down He had been soldier and doctor and he had covered himself with the glory of both professions Replying to the toast Dr Reynolds spoke reminiscently, and dwelt on the example of his old teachers and friends at Epsom College their encouragement and stimulation had been an influence to him all his life Going on to propose the toast "Floreat Epsomia" he said that since its foundation in 1850, the school had had a proud record during the great war 145 had laid down their lives and as years went on the loss of old and beloved masters created blanks which could never be filled For the present the school was steadily prospering and in the future he was certain that it would go from strength to strength In reply Mr A C Powell the head master reviewed the work of the year and spoke of both academic and athletic distinctions The Old Boys' Club now numbered almost a thousand members, and was still growing The financial position of the school was sound They had had a very successful year and he hoped that before long they would be able to accommodate 450 boys in the various houses Mr G E Neligan proposed the health of the guests to which Lord Burnham and Lord Dawson of Penn replied In commenting on the position of medicine to-day, Lord Dawson said that tradition must be maintained, but all must be prepared to dispense with the thing that did not matter The doctors of the future would probably have to concentrate on prevention rather than on the treatment of disease Recent legislation had resulted in the provision of many new hospitals, and the question of staffing these was one in which the guidance of the medical profession must be sought It was the duty of the profession to have a satisfactory and efficient medical policy He had profound faith in its future

Clinical Laboratories in Hospitals.

At a meeting of the Liverpool Medical Institution, held on December 4th, Dr E Cronin Lowe read a paper entitled 'The relation of the clinical laboratory to the general hospital" This relationship, he said, had greatly developed on account of the many modern advances in the investigation of clinical problems from both the bacteriological and pathological aspects After outlining the many activities which present-day requirements in clinical research demanded, he remarked upon his personal experiences in the activities of the clinical laboratories in the Liverpool and Southport districts Apart from the investigation of in patients, the clinical laboratory dealt with the out patient class of case, undertaking tests of gastric, hepatic, pancreatic, or renal function, and also bacteriological investigation of cases suspected to be suffering from some form of focal infection Dr Lowe described a scheme of clinical and pathological overhaul and emphasized the importance of cytological and biochemical examination of the blood condition of such patients, thereby obtaining the opportunity of detecting associated derangements which frequently indicated helpful lines of collateral treatment In emphasizing the importance of examinations for evidence of focal infection he described the practical utility of the pathogen-selective method in bacterial investigations, and, further, the value which the method provided, on later repetition of obtaining evidence of improved immunity, or otherwise, in the cases concerned He also said that the modern clinical laboratory attached to the general hospital should become a treatment centre for such cases as were detailed to it and his experience was that valuable results were only thus obtained, as the patients were under the observation of both clinical pathologist and clinician The establishment of such departments necessitated an equipment and staff capable of undertaking full bacteriological and pathological investigations upon the ordinary type of clinical specimens There should also be examination and treatment rooms The steady increase of activities in the centres developed during the past ten years was definite evidence, not only of the practicability of such a scheme but of its utility to the clinical departments of the general hospitals with which they were associated

Medico-Legal Society Annual Dinner

The annual dinner of the Medico-Legal Society took place at the Holborn Restaurant on December 12th with the Right Hon Earl Russell presiding Sir William Willcox voiced the general regret at the absence through illness of Lord Riddell the society's president He went on to propose the usual toast of "Medicine and Law" comparing and contrasting the two professions Both of them he said, were jealous mistresses neither of them to be taken up without a definite call But they were different in the respect that medicine was ever changing to keep pace with science, while law moved only slowly from precedent to precedent Dr R A Young President of the Medical Society of London, whose name was associated with the toast, also said that the two professions had many things in common He noticed that only the other day the head master of Harrow Dr Norwood had said that both medicine and law, like mathematics, were accurate

professions Dr Young did not know who it was, but he was sure that was a mistaken view of the profession of medicine It was not an accurate profession, and the sciences on which it was founded were constantly in a state of variation Of three subjects he thought the members of the two professions would never agree—namely, as to the signs of intoxication, as to the criteria of insanity, and as to the right of the medical profession to claim the privilege of professional secrecy Sir Thomas Hughes, Chairman of the General Council of the Bar, who also responded to the toast, took occasion to remark on Mr Justice McCardie's recent pronouncement, in his Maudsley Lecture, on the widespread extent of perjury There was some substratum of truth in Mr Justice McCardie's complaint, but he thought it rather exaggerated It had to be remembered that of recent years an accused person was allowed to give evidence on his own behalf, and the same standard of truth could not be expected from a person in that position as from the ordinary witness, but, save in that respect, he doubted whether perjury existed to the extent which the learned judge had supposed Mr E H Tindal Atkinson, Director of Public Prosecutions, in proposing the health of the society, referred to his earlier experience as a referee under the National Health Insurance Act This had introduced him to some curious byways of general practice, but it had inspired him with great respect for the very able doctors whom the Ministry of Health had appointed to sit with him as assessors In some amusing references to medical terminology, Mr Tindal Atkinson said that in the reign of Elizabeth, if a coach had run over someone, the local leech would have reported to the coroner, had there been one, that the deceased "was considerably injured in his liver and lights" Nowadays when he received a report on a motor manslaughter case the reference to the liver might still remain, but the reference to the "lights" had given way to other anatomical descriptions, not so illuminating, which made him search his memory for forgotten Latin and Greek He added that when he read the reports on manslaughter cases (including long statements of witnesses who were always prepared to give him a theory as to the blame for the accident (forgetting that that was the duty of the jury), he turned with relief to the medical reports, where certainly he got medical theory, but also, what he most valued, absolute impartiality The doctors in this country being what they were, there was little danger of such a verdict being returned as was once returned at an inquest in Ireland "The deceased undoubtedly committed suicide, but his end was hastened by the post mortem examination" Earl Russell, in responding for the society, mentioned that twenty-three new members had been admitted during the year, bringing the membership up to over 400 He exhibited the president's new badge, a very beautiful piece of workmanship The health of the guests was proposed by Sir Albion Richardson, and Sir Alfred Tobin, Treasurer of the Middle Temple, and Lieut Colonel C T Samman, Master of the Society of Apothecaries made brief replies

Correspondence.

THE STETHOSCOPE AS AN AID TO PERCUSSION

SIR,—It is perhaps a bold thing to suggest any new method in the practice of percussion At various times attempts to promote skill in the art, and the attainment of confident results, have taken the form of specialized plexors and pleximeters, and auscultatory percussion and the combination of the stethoscope and the tuning-fork are further modifications which claim value in these respects Yet for the most part the simple original procedure holds the field In actual practice there is probably in every performer a gradual and perhaps unconscious development of some individuality of method and of judgement, so that for him his personal procedure yields fairly satisfactory results None the less it remains true that in no fashion of physical examination is a high level of efficiency so difficult to attain, and in no method is the performer more likely to fall into some degree of self-deception I have this latter consideration well in mind when I draw attention to a simple development in which I have convinced myself there is decided helpfulness This is to wear the binaural stethoscope when practising percussion The bell of the stethoscope is not placed on the patient's body, but is allowed to dangle, as one may say in the air, while the earpieces are worn in the usual fashion, a considerable shortening of the india-rubber tube makes for convenience, but is by no means essential Under these conditions the quality of the response to the percussion stroke appears to me to gain in distinctness, and there is increased sharpness in defining areas of dullness and in recognizing contrasts between the percussion qualities of neighbouring organs Whether these results are due to the exclusion of other noises by the earpieces or whether the bell of the stethoscope has some resonating virtue I cannot say but as an aid to confident percussion this simple device is well worth cultivation I have tried bells of various sizes and shapes, and also a support to keep the bell immediately over the part of the body under examination, but in the end the simple binaural stethoscope used as above described proves quite satisfactory, and I venture to commend the method as suitable for experiment Naturally a little patience and attention are needed at the outset but, given these qualities, I think that what is here described will be found a decided help to a confident percussion judgement As the publication of Dr R A Young's extremely interesting presidential address on "The Stethoscope"[1] is just now engaging attention, the occasion tempts me to put into print a suggestion to which in less formal fashion I have sometimes invited the attention of my colleagues

I venture another allusion Dr Young describes various complicated forms of stethoscope, and also mentions resort in an emergency to such handy tools as a wine glass or a thermos flask Some years ago, in the *British Medical Journal* of March 4th, 1916, I drew attention to the ready service which a cylindrical urine test glass can render in this direction, and I add some others Thus, by grasping the cylinder and using the edge of the rounded base as a hammerhead a plexor for heavy percussion is provided Employed, too, in this way the glass is exactly the apparatus required to provoke the knee-jerks and heel jerks, as well as the tendon-jerks of the upper limbs, while the "spout" offers itself invitingly when the enterprise of the plantar reflex has to be undertaken Again, rolled over the surface of the skin, the cylinder differentiates haemorrhagic and pigment spots from spots due to congestion and inflammation, and, once more, the glass is a convenient object for the patient's grasp when intravenous medication or venesection has to be undertaken There remain the specific purpose for which the glass was called into being, its modest price its cleanly quality, its readiness for service It is a modest form of apparatus, but its clinical values are both numerous and varied—I am, etc,

London W 1 Dec 9th C O HAWTHORNE

RESULTS OF TREATMENT OF CANCER

SIR,—Dr Russell Green in his letter in the *British Medical Journal* of November 29th (p 932) says "It is important that the advance of radiology should not be held up by a barrage of fallacy," in which everyone will agree, but he then goes on to depreciate the results attained by operation for cancer of the breast, as shown by the Birmingham Branch of the British Empire Cancer Campaign (Report 1927, p 59) May I explain that a special officer, Dr Lunn, was appointed to collate all cases of cancer of the breast operated on between the years 1910 and 1920 at the General the Queen's, and the Women's Hospitals The total number of cases was 799 In 258 of these cases no microscopic report was obtained, and to ensure as complete accuracy as possible these cases

[1] *British Medical Journal*, October 18th, 1930

were not pursued the scope of the inquiry being limited to 541 cases in which microscopic reports were available Of these 34 could not be traced by Dr Dunn, by the medical officer of health or by the Registrar General The report therefore dealt with 507 cases and it was shown that at the end of three years 54 per cent, at the end of five years 40 per cent, and at the end of ten years 30 per cent, were alive and well These results are fully supported in the Ministry of Health Report No 51 (p 93) by Dr Janet Lane Claypon The statement by Dr Green that "the total number of cases operated on was ignored" is not true as the report shows, and it is strange that Dr Green who is a member of the local committee should now for the first time challenge the report and did not comment on the figures at the meetings

Dr Green quotes figures from Swedish sources showing results at a five year period after operation, the freedom from recurrence varying from 15 to 20 per cent, and then builds up statistics which are based upon figures, some imaginary and others that cannot be tested, his object being to depreciate the value of the results obtained by Birmingham surgeons Confirmation of the 1927 report is fortunately provided by an inquiry undertaken by Mr Percival Mills in 1921, published I believe, in the *British Journal of Surgery* Mr Mills investigated the cases of cancer of the breast operated on at the General Hospital He adopted a six-year period and found that 38 per cent remained well after that lapse of time At the same time he inquired into the results obtained from my private cases every one of which was investigated microscopically, of these 48 per cent remained well at the end of six year

As a further confirmation the history of a group of 5 of my patients, all doctors' wives may be quoted in 1923 3 were alive and well twenty-three, twenty and fourteen years respectively after operation, although two had infected axillary gland The other 2 developed metastases and died one year and three years respectively after operation —I am, etc,

GILBERT B PEIRCE
Edgbaston Dec 9th Chairman Birmingham Branch British Empire Cancer Campaign.

SURGICAL TREATMENT OF CHRONIC DUODENAL ULCER

SIR,—In the matter of treatment of chronic duodenal ulcer to-day almost all the leaders in the field of gastro-duodenal surgery advocate a short-circuiting operation, with or without some form of direct attack upon the ulcer itself such as infolding or invagination cauterization, or local excision Partial duodenectomy has been introduced during the last few years In dealing with a perforated duodenal ulcer one of the simple methods of closure of the opening will not only bring about a cure of the symptoms but also the disappearance of the actual ulcer mass this is of course an accepted and proved fact about which there can be no dispute The way in which this occurs is a matter for speculation but it may be that a new and vigorous peritoneal base is created which with the well-known phagocytic action of that tissue results eventually in the demolition and absorption of the mass

The question arises What is the difference in structure between the non perforated and the perforated ulcer? The answer is that except for the opening in the peritoneum, there is no difference it is purely a matter of the depth of penetration of the ulcer into the layers of the gut It is said that in the latter type there is an absence of granulation tissue the effect of which however can in no way alter the ultimate disappearance of the ulcerous tissue which follows simple infolding This being so why is it that so serious an operation as one of those mentioned in the first paragraph is recommended to us as being the only treatment for every case of non-perforated ulcer when quite a large number lend themselves to safe, easy and deliberate perforation with the cautery thus bringing them within that category which can be dealt with by simple suture? If this treatment does all that is necessary in the perforated type then it is safe to assume that this same treatment, applied, after due attention to any possible sites of infection elsewhere to the non perforated ulcer, will give the desired result This, indeed, is what I have found in my own cases, which are, however not numerous But is one to wait until a series of a hundred cases has been completed and ten years have elapsed after the last one, before making known the results?

In view of this I would go so far as to state that the wholesale use of the more severe and serious operation is not justified and that it should not be used for those ulcers situated on the anterior wall which are easily accessible, single, and more than half an inch from the pyloric ring The opportunities for applying the minor method will be found to be numerous The variety of operative procedures propounded by our leaders—and vigorously taught by their disciples—is in itself proof of the prevailing uncertainty as to the treatment of duodenal ulcer, the pathology of which is obscure and the cause unknown Even the manner in which a gastro-enterostomy acts in its curative effect is after many years, still in dispute among those who so ardently advocate its use

Although it has been said that abdominal surgery has reached a point of advance beyond which we cannot hope to go—and we accept this—any improvements which are likely to be evolved on the basis of our present knowledge can only be anticipated by minutely traversing the old paths which have led to that very end It seems that in the suggestion which I submit implying as it does safety, simplicity, and effectiveness, there are at least possibilities —I am etc,

Leigh Lancs Dec 4th. DONALD MACLEOD F R C S

NON-SPECIFIC PROTEIN THERAPY IN ELEPHANTIASIS

SIR,—In the *Lancet* (January 11th, 1930 p 72), together with Dr Strangways Dixon, I reported a series of cases of elephantiasis treated by protein shock In some of these no beneficial results were obtained but I have gone on with a similar treatment in other cases in order to get larger figures to work upon for reliable statistics I expressed the wish that other workers would also try the method in the hope of obtaining some definite proof I am therefore interested in Dr McGolrick's case from Weihaiwei reported in the *British Medical Journal* for December 6th (p 957) Here larger doses of the vaccine were given than usual (maximum 800 million), and also at more frequent intervals The results seemed to be good a steady diminution in the size and a marked change in the consistency of the leg taking place Due prominence is given to the part that the elastic pressure played in the result but Dr McGolrick is convinced that this alone could not have produced such a favourable effect in so short a time He stresses the larger doses of the vaccine and the shorter intervals

The case, as I have said, is of interest and compares favourably with some of those in my series but here, as in most of my cases, the end-results have not yet been followed up and until they are one cannot definitely decide as to the efficacy or otherwise of this new form of treatment for elephantiasis Again one hopes that observers will try the method and report their results —I am, etc,

London W Dec. 8th G CARMICHAEL LOW

TEMPORARY TREATMENT WITHOUT CERTIFICATION

SIR,—A correspondent in your issue of December 6th wishes for the official interpretation of the Board of Control of the term 'incapable of expressing himself as willing or unwilling to receive treatment" This can be found in the report of the proceedings of the conference on mental treatment published by H M Stationery Office, on page 64 of which Sir Hubert Bond, a distinguished member of the Board says of the incapacity to express willingness or unwillingness to receive treatment," that 'to attempt to strain these words, and to bring within the section cases that in fact are unwilling to receive treatment in the place selected, and that ought to be certified will be both improper and most unwise this is a lesson which

I am sure we should all take to heart, it is one wherein, as to the decision to be taken before reception, the fact that one of the recommending physicians must (Subsection 3) be a practitioner approved for this duty should prove of signal value" On page 65 he says, 'mental conditions, which may render the patient incapable of expressing himself as willing or unwilling to receive treatment, may be sudden in onset and may be the first indication of mental illness as, for example, during the puerperium or in the course of severe toxæmia or occasionally following upon a severe mental shock In all such cases, where removal from home is necessary, resort to the procedure for 'temporary treatment without certification' seems indicated" I take it that these statements of Sir Hubert Bond express the views of the Board of Control or are an "official interpretation"—I am, etc,

Cheadle Royal, Dec 9th L HARRIS-LISTON

FLAVINE AND GLYCERIN IN MIDWIFERY

SIR,—I was much interested to see in the *British Medical Journal* of December 6th (p 980) a letter by Dr Mackinnon of Oldham advocating the use of glycerin in labour For nearly two years I have been working and trying to find a suitable antiseptic to use with glycerin for vaginal injection in cases of labour for I was of opinion that if one could keep a viscous hygroscopic fluid like glycerin impregnated with a potent antiseptic in close contact with the parturient passage during labour, it would diminish the chance of infection from without, and also from the vagina Early in 1929 I was in correspondence with Mr W H Martindale, F I C, F C S, on this subject, and I suggested using phenol and glycerin Mr Martindale very kindly gave me his valuable advice, and tested the bactericidal power of phenol in water and glycerin His experiments proved that phenol in glycerin is two and a half to three times *less potent as an antiseptic* than in aqueous solution We therefore came to the conclusion that the strength of phenol to be potent as an antiseptic would be too irritating for the delicate tissues of the vagina

Professor C Oldfield of Leeds, to whom I was kindly referred by Lord Moynihan, quite approved of the idea, but suggested the use of acriflavine, as being less irritating to the tissues and equally effective as an antiseptic I am grateful to him for his advice, of which I have gladly availed myself

The suggestion was that prior to any vaginal examination a *vaginal injection of flavine and glycerin* should be given this injection to be repeated prior to any manipulative or operative intervention, and to be repeated at the end of the labour, the injection to be given under the strictest antiseptic precautions, and, as Professor Oldfield suggested by the person who is to make the examination or perform the operation

I wrote a short paper last year embodying this suggestion, and also a few others, the principal other one being the *continuous administration of calcium salts from the commencement of the pregnancy to the end of the puerperium*, with the object of abolishing the calcium deficiency and building up the resisting power of the individual This paper has not so far been published In the meantime I hope that the suggested treatment—continuous administration of calcium salts and the use of vaginal injections of flavine and glycerin in labour—may be given a trial Surely in the fight to reduce maternal mortality any reasonable logical method is worthy of a fair trial It is with this object and because the Maternal Mortality Committee (to whom the paper had been sent) advised me to publish it in the medical journals, that I write this letter I am etc,

Congleton, Dec 8th J L MOIR, M B, Ch B

SIR,—The use of glycerin as a routine dressing for perineal wounds in midwifery, as described by Dr Mackinnon in your issue of December 6th, is interesting, and would appear to be as efficacious as a rather more elaborate preparation which I have been in the habit of employing This preparation is as follows acriflavine 1/2 grains, paraffin liq 2½ ounces, cera alba 40 grains, aq dest 5 drachms It is applied on gauze strips

Flavine (or acriflavine, diamino-methyl-acridinium chloride) acts as a bactericide in a concentration 400 times lower than that required to interfere seriously with phagocytosis The dressing is also largely waterproof, and thus *protects* the devitalized perineal tissues from the softening and infective action of the secretions found in this region It further counteracts the *irritation* commonly experienced from the sutures themselves Cases treated with this method, like that of Dr Mackinnon, show no signs of sepsis—I am, etc,

Newhall, Dec 6th E M R FRAZER

NOCTURNAL INCONTINENCE IN CHILDREN

SIR,—I thoroughly agree with the communication by Dr J Perceira Gray in the *Journal* of November 29th on the subject of nocturnal incontinence in children It is a treatment I have adopted for over a year The cause of this condition is not thoroughly understood hence the many *failures of treatment* In all my cases for the last ten years I have had the eyes examined for errors of refraction, and, if required this has been remedied by suitable glasses The tonsils and adenoids have been removed and circumcision in boys has always been performed *In none*, however, *did a cure result* I met Colonel McCarrison ten years ago, and he suggested that the condition might be due to *small vesical ulcers* of vitamin-deficiency origin for he had several times in his experiments on animals found vesical ulcers to be associated with vitamin deficiency Since then I have always cystoscoped my patients, but in every case have seen a perfectly healthy bladder, *completely devoid of ulceration*

About six years ago a neurologist with whom I was discussing the subject, said that he treated these *patients* successfully with thyroid extract because in a number of cases the pituitary fossa was shown by x rays to be enlarged Since then I have had all my patients x rayed, and it was always reported that the pituitary fossa was normal in size I also found thyroid extract in these cases of little therapeutic value Discussing this with Dr Miller, radiologist to All Saints' Hospital, he informed me that he had seldom seen the pituitary fossa enlarged but had noticed in a large number of cases the presence of spinal spina bifida occulta The x rays I have taken since, both at All Saints' Hospital and at St Mary's Children's Hospital (Plaistow) confirm his observation It is probable, therefore that nocturnal enuresis in children is due to a delayed development of the autonomic nervous system and even as re-education is useful in the treatment of tabes dorsalis, so voluntary vesical education, by hastening the development of vesical reflexes can cut short the period of enuresis—I am etc,

London, W 1, Dec 5th F MCG TOUCHMAN

AVERTIN ANÆSTHESIA

SIR,—I have read Dr Langton Hewer's letter in your issue of November 29th and note what he says about Mr Howard Jones's work on high spinal block with percaine I saw percaine used in Vienna (not as a spinal anæsthetic) over a year ago, and I was not altogether impressed with its value Just prior to this I witnessed high spinal anæsthesia in Bucarest, where novocain is employed I was able to obtain opinions and literature I can find no allusion to monæmia Before the introduction of avertin to this country I was constantly using spinal anæsthesia (stovaine) for operations upon the stomach and gall-bladder, where a preliminary dose of 1/6 grain of morphine had been administered I cannot recall a single case of monæmia under these conditions Since the arrival of avertin I have used this drug in combination with spinal anæsthesia (both stovaine and spinocain) for major operations in the neighbourhood of the diaphragm chiefly partial gastrectomy, gastro-enterostomy, and cholecystectomy but without the use of morphine I have never witnessed any symptoms of anoxæmia, and after a very considerable experience I am at a loss to explain them Patients in my clinic (and I am sure the same obtains in Dr Hewer's clinic) are very carefully examined as to the kidneys, liver, and heart function before avertin is administered, the dose of avertin

per body weight is checked by a second person and the avertin is tested with Congo red for each dose given

In the fatal case mentioned by Dr Hewer two important questions arise (1) Was morphine or any derivative given previously, immediately, or remotely? (2) Was the correct dose of avertin administered to a suitably receptive patient In over two and a half years' experience using avertin in combination with field blocks spinal blocks, and very light ether anaesthesia, I have not yet had any disconcerting experience in the form of anoxaemia or deaths Perhaps I have been lucky but I feel sure the luck has accrued from not using this drug indiscriminately from not using it injudiciously in conjunction with morphine or chloroform or any drug which is going to hinder its excretion or likely at the time to depress the vital centres The ideal is undoubtedly the combination of avertin with gas and oxygen as I saw it used by Sir Francis Shipway There was no evidence of anoxaemia

In your issue of December 13th Dr F B Parsons suggests that I am unacquainted with the German literature on avertin and quotes from a paper written by Haas (*Deut med Woch*) and published in 1927 I should like to disillusion Dr Parsons of this suggestion, as I have waded through much German literature on the subject Further the year of the publication referred to was the very year I took the trouble to go to Germany to see avertin *used so as to find out at first hand what its* clinical properties really were The avertin then used was the solid form and it was being used in combination with very light ether inhalation (amnesic dosage) or to be more lucid dosage very far short of that required to produce full or complete surgical anaesthesia" I asked why ether was necessary, and was informed that avertin was a basal narcotic that by itself, in safe dosage to the patient, was insufficient to produce complete surgical anaesthesia This very fact is stressed all through the pages of the pamphlet issued by the manufacturers —I am, etc,

Bradford. BASIL HUGHES

PARTURITION PER PERINEUM

SIR,—I have been much interested in the memorandum by Drs Tindal and MacLennan on a case of parturition per perineum, published in your issue of November 22nd (p 863), and in the correspondence which has ensued Some of these cases are undoubtedly due to a contraction of the transverse diameter of the pelvic outlet, the effect of which is to narrow the pubic arch This leaves insufficient space for the presenting part to emerge directly beneath the symphysis pubis and it is pushed further and further backward until in extreme cases delivery takes place in what Klein describes as the posterior sagittal diameter of the outlet The fact that there had been an extensive tear at the previous confinement in the case recorded by Drs Tindal and MacLennan suggests the presence of a contraction of this type It would be of interest to know whether such a condition was noted in any of the cases described by your correspondents —I am etc,

Derby Dec. 8th GERALD F KEATINGE, M D
Honorary Assistant Surgeon Derbyshire Hospital for Women.

Obituary

ANDREA RABAGLIATI M D, F R C S,

Consulting Gynaecologist Bradford Infirmary and Consulting Surgeon Bradford Children's Hospital

WE regret to record the death on December 7th of Dr Andrea C F Rabagliati after a long and distinguished career He was born in Edinburgh in 1843 His father, an officer in the Italian Army, was engaged in the earliest insurrection against the Austrian domination, and on the failure of that attempt fled to Scotland He stayed for some time at the manse in Kelso, and then went to Abbotsford, reading Italian with Sir Walter Scott Subsequently he settled in Edinburgh and married a Highland lady

Andrea Rabagliati was educated at the Royal High School after which he stayed for two years with an uncle in British Guiana returning in 1862 to study medicine at Edinburgh University, and graduating M B in 1869 In 1872 he proceeded M D with first-class honours, and won the gold medal for a thesis on relapsing fever In 1890 he obtained the Fellowship of the Royal College of Surgeons of Edinburgh After graduating Dr Rabagliati became assistant to the late Dr Leeson medical officer to the Bradford Workhouse He was appointed assistant medical officer to the workhouse, and in 1870 became house-surgeon to the Bradford Infirmary a post which he held for two years In 1872 he began private practice, speedily coming to the front rank of Bradford medical men In 1877 he was appointed surgeon to the Bradford Infirmary assistant surgeon to the Eye and Ear Hospital and medical officer to the Bradford Fever Hospital In 1882 a small children's hospital originally with only twelve beds for incurables, was opened in Hanover Square by private enterprise to supplement the provision for children in the Bradford Infirmary, but encountered considerable opposition Dr Rabagliati strongly sympathized with the undertaking and in conjunction with Dr Burnie and the late Dr Harry Meade, gave it all the help in his power In 1887 the hospital moved to larger premises in Springfield Place and a scheme was set on foot to build a large and properly equipped children's hospital The present institution, which has been considerably expanded was opened in 1890, and Dr Rabagliati was appointed consulting surgeon

Dr Rabagliata was instrumental with the untiring help of his wife in establishing St Catherine's Home for Cancer, and when this was opened he was appointed consulting surgeon He was also consulting surgeon to the Bingley Hospital senior physician to the Actors' Association London, and to the Music Hall Artistes' Association London and consulting gynaecologist to the Bradford Royal Infirmary Although he held so many surgical appointments his bias was always towards medical practice which interested him greatly and more and more he was consulted in medical cases especially with reference to diet He published numerous books on this subject and built up a large consulting practice on dietetic lines he was often urged to give up all general practice and confine himself to consulting work That he did not definitely take this step was thought by many to be a mistake but he held strong views about the responsibility of medical practice, and believed that he could do more good by the general care and guidance of patients whose cases were well known to him than by occasional specialist advice However, in spite of himself his consulting work rapidly increased, he had also a heavy load of correspondence and so the general practice side of his work was virtually squeezed out He continued in his profession without intermission taking but few holidays, from 1872 until his 87th birthday in May 1930 when he was first taken ill After a week or two he resumed his work, which he continued until the end of July, when the state of his health forced him to abandon practice, to his bitter disappointment

Dr Rabagliati took a great interest in the work of the British Medical Association He was a member of the council of the Yorkshire Branch from 1883 to 1892 president of the Branch 1893–94, and vice president from 1895 to 1915

DR HALLIDAY SUTHERLAND writes In his early professional life Dr Rabagliati realized that many chronic ailments arise from excess of food products which stagnate in the lymphatic system To overcome this condition he placed his patients on a starvation diet The value of that treatment in suitable cases is now recognized but when Dr Rabagliati acted on his conviction it entailed the loss of a large practice This was gradually rebuilt on lines in which he believed to the end His books did not reach a large circle of readers The style in which they were written belonged to an earlier period, and their author was fond of coining new words based on Greek roots, which puzzled the non-classical reader When more is known about the role of the lymphatic system in the causation of disease A C F Rabagliati will rank as a pioneer

HUBERT PINTO-LEITE, B.A., M.R.C.S., L.R.C.P.,

Anaesthetist to the Westminster Hospital and the Lyclina Hospital for Sick Children

WE much regret to announce the death on December 12th in London, after a long illness, of Dr. Hubert Pinto Leite, at the age of 51. He was the eldest son of the late Joaquim Pinto-Leite, Portuguese Vice-Consul in Manchester, and received his early education at Beaumont and Stonyhurst, entering Caius College, Cambridge, as a medical student in 1899. At Cambridge he was well known in musical circles as a tenor soloist and member of the "Caius Quintette." Having graduated B.A. with honours in the Natural Sciences Tripos, he joined St. George's Hospital, and obtained the M.R.C.S., L.R.C.P. diplomas in 1908. Then, after serving as house-physician and house-surgeon at St. George's, he began private practice in Fellows Road, Hampstead, and was soon appointed honorary anaesthetist to the London Throat Hospital and to the National Dental Hospital. For several years before the war he had held a commission as lieutenant in the R.A.M.C. (T.F.) and was mobilized in August 1914 with a field ambulance attached to one of the London Territorial divisions. His war service overseas included duty as registrar of the 43rd Indian General Hospital, officer in charge of the Medical Division of No. 44 Stationary Hospital, L.L.E., and D.A.D.M.S. with the acting rank of major. He was awarded the Territorial Decoration. Returning to civil life after the war, Dr. Pinto-Leite added steadily to his reputation as a skilful administrator of anaesthetics, and in that capacity was elected to the honorary staffs of the Westminster Hospital, the Lyclina Hospital for Sick Children, the Hospital for Women, Soho Square, the Golden Square Throat, Nose, and Ear Hospital, and the Royal Dental Hospital. When the British Medical Association held its Annual Meeting in Glasgow in 1922 he was honorary secretary of the Section of Anaesthetics, and for a number of years he was a valued occasional contributor of notes and reports on this subject in our columns. His only signed contribution to medical literature was a paper published in the *Westminster Hospital Reports* for 1925 on "Lung complications disclosed post mortem after surgical anaesthesia." Before the onset of his last illness Dr. Pinto Leite undertook part-time duty as medical superintendent of the Hospital of St. John and St. Elizabeth. He was also honorary secretary of the Society of Members of the Royal College of Surgeons of England.

Hubert Pinto-Leite, known affectionately to all his intimates as "Pinto," was a most generous warm-hearted friend, loyal and unselfish, diligent in well-doing, a man who could be relied on to carry out faithfully and punctually every task he undertook, without regard to his own interest.

By the death, at the age of 83, of Dr. C. Henry Phillips at Bournemouth on November 23rd, medicine has lost one of the finest type of general practitioner. He studied at Owens College and became L.S.A. in 1875, M.R.C.S. in 1876, F.R.F.P.S.Glasg. in 1885, and M.D. of the University of Durham in 1894. For over forty years he had a large practice in Hanley, Stoke-on-Trent. For thirty-six years he was medical superintendent of the Stoke-on-Trent Infectious Diseases Hospital at Bucknall, and for twenty years held a similar office at Dagnall Small-pox Hospital. He was a justice of the peace for Hanley for twenty-nine years, and also a member of the school board and of the town council. A colleague writes: When a practitioner covers so wide a field of work as did Dr. Phillips it might be thought that much of his knowledge would be superficial, but this was not the case. He contrived by dauntless energy to acquire as deep a knowledge of several branches of medicine as most can attain merely of one. He kept abreast of modern methods and until blindness afflicted him five years ago was an excellent bacteriologist. Of unassuming disposition, he did not think of himself as a teacher but was a much greater one than he knew, not realizing how absorbing to younger practitioners it can be to hear discourses upon typhoid or small-pox from one who can number his cases of these now rare diseases by hundreds or even thousands. He had notes of 3,700 mid-wifery cases which he considered presented some point of interest, and until he retired from practice eight years ago never spared himself in this branch of work. The financial aspect of medicine did not concern him greatly. The patient most in need of his care was the one who invariably got it. His day would be amazingly varied. After a night spent with a case of difficult labour the day might find him amputating a leg down a coal mine, then rushing to the fever hospital to perform a tracheotomy, in addition to attending to the many calls of a large panel practice. He bore his five years of blindness with much uncomplaining patience, though it must have been a great trial to a man still so interested in his profession, and who had planned to spend his well-earned leisure in further study of it. The sympathy of a large circle of friends will go out to his widow and daughter.

Dr. Charles Scott Kilner, who died on December 1st at his residence in Bury St. Edmunds, at the age of 77, was one of the most popular medical practitioners in West Suffolk. He received his medical education at Edinburgh, where he studied under Lister, and graduated M.B., C.M. in 1876, he obtained the D.P.H. Camb. in 1899. After acting as assistant at Oundle and Burton-on-Trent he returned home to Bury St. Edmunds in 1878 to join his father in practice. For more than fifty years he was a medical officer of health and public vaccinator for two districts of the Bury St. Edmunds Union, and on his resignation two years ago he received a presentation from the Board of Guardians to mark the devotion he had shown to this side of his medical work. At the time of his death he was medical officer to the Thingoe Rural District Council and had a very thorough knowledge of social conditions in the villages. He was officially concerned with the first houses built in the county under the Housing of the Working Classes Act (1890), having always realized the importance of overcrowding in the question of ill-health. Dr. Kilner was honorary consulting medical officer to the West Suffolk Hospital, and was elected a life governor in recognition of his great services to that institution. During the war he was medical officer to the Northgate Red Cross Hospital, and in 1920 he was made a Member of the Order of the British Empire. He held the post of president of the East Anglian Branch of the British Medical Association in 1901, and since 1899 had been surgeon to the West Suffolk Constabulary. He was appointed a magistrate for the borough of Bury St. Edmunds in 1916, and actively identified himself with various social and religious activities in the town. He is survived by four daughters and two sons, one of whom is in the medical profession.

Dr. Ronald T. Herdman, deputy medical officer of health for Bedfordshire, died suddenly on December 5th. He appeared to be in his usual health that morning and among other duties attended a meeting of the County Education Committee. He was born in October 1872, and studied medicine at the University of Edinburgh, graduating M.B. in 1894. He proceeded M.D. in 1910, and obtained also the Cambridge D.P.H. On leaving Edinburgh he devoted special attention to diseases of the ear, nose and throat, and, after holding a house appointment at the Surrey County Hospital, was house-surgeon at the Throat Hospital, Golden Square, London. During the South African war he acted as a civil surgeon, and served in France with the rank of temporary lieutenant R.A.M.C. during the late war. He was appointed deputy medical officer of health and school medical officer by the Bedford County Council in 1912, when the duty of examining elementary school children was first placed upon the county and borough councils. Outside his professional work Dr. Herdman's chief interest was in the British Legion, and he attended the annual dinner of the Bedford branch on the evening of his death. He was a member of the British Medical Association and a Fellow of the Society of Medical Officers of Health. By his death the county loses one of its most conscientious and public-spirited officials.

The town of Aberdeen and the medical profession have sustained a severe loss in the recent death of Dr DAVID WATSON CEDDIE consulting physician to the Royal Aberdeen Hospital for Sick Children. A son of the manse, Dr Ceddie was born in 1864, his father being for many years Free Church minister of Banff. After graduating in arts and medicine in the University of Aberdeen he was for several years assistant to the late Dr Miller of Fort William, and the rest of his life was spent in general practice in Aberdeen, where he was anaesthetist, and subsequently physician to the Children's Hospital. As a practitioner and as hospital physician and teacher he gave of his best to his patients and students. His sound practical knowledge and his gift of lucid exposition gained for him well merited appreciation. A man of wide culture and an artist of no mean ability, he had wide interests and a broad and sympathetic outlook on life. The fine qualities of his character were displayed in his unselfish devotion to patients of all classes, and in the way in which he was always able to give help and advice to his younger colleagues. To have known him well was a great privilege, and is now a happy and inspiring memory. To his widow and family his many friends tender their deepest sympathy. Dr Ceddie was a member of the Aberdeen City Division of the British Medical Association, and was President of the Aberdeen Branch in 1925–26.

Medico-Legal

THE MARKING OF SURGICAL GOODS

INSTRUMENT MAKERS LTD

BOARD OF TRADE summonses under the Merchandise Marks Act were heard at Marlborough Street Police Court on December 10th against the Surgical Manufacturing Co. Ltd. of Mortimer Street, W. Two summonses alleged that the company advertised or offered for sale under a specific designation by means of an illustration and written matter in a catalogue certain imported goods of a class to which an Order in Council under the Merchandise Marks Act, 1926, applied, and that the company did not include in such advertisement an indication of the origin of the goods. A third summons alleged that the company sold certain imported surgical articles which did not bear an indication of the origin. Mr G. B. McClure appeared for the Board of Trade, and Mr J. N. Nabarro represented the company.

Mr McClure stated that on July 15th a Dr. Hayward sent for a catalogue of surgical goods, and it was alleged that this contained advertisements of goods of which the origin was not marked. An order for an article was given by him. On September 24th Mr. Maver, a member of a firm of surgical instrument makers, selected an article out of another catalogue and sent a messenger with the order. The article received was of foreign origin—German, he thought. The price of the article (10s. 6d.) a Mayo's needle-holder and thumb-release was such that it could not possibly be British. In October a nurse named Miss Drew went with her father to the same place and chose a dozen surgical instruments. Ten of these were foreign. If it be that this firm have made a mistake and were bringing over articles from Germany and were putting finishing touches to them they come within the purview of the Act, said Mr McClure.

Mr. A. W. Cobden, employed by a firm of surgical instrument manufacturers in St. Thomas's Street, S.E., said that on July 15th Dr. Hayward sent for a catalogue of medical goods, and one was sent to him. Advertised in it were goods which did not bear an indication of the country of origin. Answering Mr. Nabarro, who said he understood that Dr. Hayward was in the Indian Medical Service, he witness did not know if it would be necessary to have the indication of origin if the goods were to be used abroad.

Mr. E. W. Maver, a partner in the firm of Messrs. Maver and Phelps, New Cavendish Street, said that an article supplied from the catalogue to him was undoubtedly of German origin. When he first received it he sent it back, and had a letter written to the defendant company asking them to let him know whether the article was British or foreign, as their firm had to declare it under the Merchandise Marks Act. They received back what appeared to be the same instrument, but it had a little tab "Surgical Manufacturing Co. Ltd." and the word "Foreign" attached to it.

Mr. Nabarro: When it was observed that this article was foreign it was marked accordingly.

Mr. Nabarro said that the defence in regard to the catalogue was that, as it was for a doctor in India, it was not necessary for the articles to be marked with the country of origin. With regard to the summons relating to the sale of articles to Miss Drew, two of the articles were undoubtedly British. As to the remainder, they were certainly unmarked, and he pleaded guilty.

Evidence was given by Mr. W. E. Birch, employed by the defendant company. He said that some thousands of these catalogues were printed and dispatched early this year before arrangements were made with the Board of Trade to insert slips indicating articles which were of foreign manufacture. Since then the catalogues had been bound with the slips inside.

Mr. Nabarro submitted that no great harm had been done, and asked the magistrate to impose a nominal penalty.

The Magistrate (Mr. R. E. Dummett): There is no doubt whatever in my mind there has been an infringement of the Act and an attempt on the part of the company to pretend that the bulk of the goods were of British make when in fact they were not. He imposed a fine of £2 with £2 2s. costs on the first summons, £2 with £10 10 costs on the second summons, and 10s. with £3 3s. costs on the third summons.

Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

THE adjournment of Parliament for Christmas was fixed for December 19th. Earlier in the week the Government proposed to complete the passage of the Education (School Attendance) Bill through the House of Commons. A debate on unemployment was also arranged. The House of Lords was occupied with the Expiring Laws Continuance Bill.

Lieut.-Commander Kenworthy gave notice that in the House of Commons on December 16th he would introduce a Vivisection Experiments Bill— to prevent the application of public money to vivisection experiments. (See *Supplement*, p. 2o1.)

Humane Slaughter

In the House of Commons on December 12th Lieut.-Colonel MOORE moved the second reading of the Slaughter of Animals Bill. He said the bill had the support of scientists, doctors and public authorities. Professor Hobday of the Royal Veterinary College, Professor Cathcart of the University of Glasgow, and Professor Barger of Edinburgh supported it. Approximately 16 000 000 animals were slaughtered each year, and the bill sought to secure that all animals were effectively stunned before slaughter. The humane killer had been made compulsory by 370 local authorities, and the bill would bring recalcitrant authorities into line. The present system caused unnecessary suffering. A report to the Corporation of the City of London, signed by the medical officer of health to the Corporation and by the veterinary surgeon to the Corporation, declared that no exception could be taken to the efficiency of the bleeding of carcases killed by the humane killer. He had hundreds of letters from medical officers testifying to the efficiency of the method of slaughter proposed in the bill. The bill exempted small farmers, peasants, and others who killed a pig at irregular intervals for their own consumption. It also exempted the Jewish and Mohammedan communities. One clause of the bill gave local authorities power to grant licences to ensure that those who slaughtered were duly qualified. Adequate inspection was proposed for the 20 000 private slaughter-houses.

Mr. LANG moved the rejection of the bill and called for a select committee to investigate the subject.

Mr. GLEESWOOD said an Act which went some way to meet the problem in Scotland had been on the Statute Book two years and worked pretty well. A growing number of local authorities had adopted by-laws enforcing humane slaughter of animals including pigs. The chief opposition came from the bacon curers.

Mr. SOMERVILLE HASTINGS said that he spoke as a surgeon. The physiology of human beings was similar to that of the larger animals used for food. Surgeons had learnt that it paid to anaesthetize, and that was what the bill proposed.

Dr. GRAHAM LITTLE said that bungling was more likely with the pole-axe than in the use of the humane killer. He pointed out that in scientific experiment on animals most careful regulations were enforced to prevent pain and suffering.

Dr. FREMANTLE, a one who had been a medical officer of health and had seen the big abattoirs of Paris and Germany, welcomed the bill.

The bill was read a second time without a division, Mr. Lang's amendment for its rejection being withdrawn.

Noxious Fumes and the Mouse Valley Foci

On December 10th Mr. MORRISON informed Colonel Howard-Bury that the first section of Battersea Power Station would be completed by the end of 1932 or the beginning of 1933. The assertion that such great chimneys emitted sulphurous fumes,

and in certain states of the atmosphere might lead to a condition such as had happened in the Meuse Valley was unsupported. The Electricity Commissioners had taken every precaution to prevent such mishap. Replying to Mr. HORE-BELISHA on December 10th, Miss SUSAN LAWRENCE said that the Ministry of Health was arranging to obtain a report of the official inquiry into the loss of life during the recent fog in the Meuse Valley. Mr. GREENWOOD informed Colonel Howard-Bury and Mr. D. G. Somerville on December 11th, that he had asked for a copy of the inquiry into the sixty-five deaths in the Meuse Valley. Until the facts were ascertained he knew of no ground for assuming that sulphuric acid or any other fumes were associated with them. Regarding the Battersea Power Station, it would be practicable to install there a plant which would reduce the emission of sulphur fumes to a negligible quantity. He considered it would be in the public interest that the report on the Meuse Valley fog should be widely spread.

Housing

Mr. GREENWOOD told Sir D. Newton on December 10th that the Exchequer contribution paid during the year 1929–30 under the Housing Act, 1919, was £6,738,118 under the Housing Act, 1923, £2,141,089, and under the Housing Act, 1924, £2,253,087. The numbers of houses completed under each Act at March 31st, 1930, were respectively 175,639, 389,193, and 232,900. Replying to Mr. Somerville Hastings on the same date, Mr. GREENWOOD said that up to October 31st, 1930, 313,862 houses had been completed by local authorities in England and Wales under the Housing (Financial Provisions) Act, 1924.

Replying to Dr. Morgan on December 11th, Mr. GREENWOOD said that up to December 1st last 258 proposals for the provision of 13,979 houses had been received from local authorities in England and Wales under Subsection (1) of the Housing Act, 1930. In addition, eighteen authorities had passed resolutions declaring areas containing a population exceeding 15,360 persons to be clearance areas, and one authority had passed a resolution declaring two areas containing 188 houses to be improvement areas. Five compulsory purchase orders and two clearance orders had been submitted to him. Under Subsection (2) of the Act, which related to urban areas with population exceeding 20,000, fifteen programmes, providing for 44,300 new houses, of which 14,923 would be allocated to the rehousing of 65,861 persons, had been submitted.

Sale of Poisons

Mr. CLYNES told Sir George Penny on December 11th that he hoped a bill would shortly be introduced to simplify and strengthen the law relating to poisons. Sir George Penny suggested that licensed vendors of arsenic, such as corn merchants, ironmongers, etc., should be made to comply with the same regulations as registered chemists. Mr. CLYNES said that the existing provisions of the law on the sale of arsenic and on poisons generally applied equally to registered chemists and to other licensed vendors. Licensed vendors were, in addition, subject to regulations made by Order in Council under Section 2 of the Poisons and Pharmacy Act, 1908.

Dangerous Drugs.—Mr. SHORT informed Dr. Fremantle on December 3rd that the report of the preliminary conference on the limitation of manufacture of dangerous drugs had been sent to the League of Nations and was in course of being printed. He could not say how soon copies would be available.

Infant Mortality.—Mr. GREENWOOD told Dr. Fremantle on December 3rd that the increase of infant mortality in 1924 was due to an epidemic of influenza and that of 1929 to a similar epidemic coupled with an epidemic of whooping-cough.

Tuberculosis.—In reply to Sir Bertram Falle on December 3rd, Mr. GREENWOOD said that persons who had received treatment for tuberculosis in sanatoriums were instructed in the precautions necessary to avoid the risk of infecting others when discharged, and it was the duty of local medical officers of health to take such steps as were necessary or desirable to prevent the spread of infection.

Schick Testing.—On December 9th Mr. GREENWOOD informed Mr. Freeman that he had sanctioned provision of facilities for Schick testing and immunization against diphtheria in thirty-eight districts in England and in two in Wales, and he had information that these facilities were also provided in other areas.

Arsenic in Sweets.—Replying to Mr. Freeman on December 10th Miss LAWRENCE said that the Minister of Health was aware of a number of recent cases of poisoning of sweets, notably by arsenic. The local authority concerned had taken suitable action, including prosecution of persons responsible. Officers of the Department had kept in close touch with those of the local authority in the course of investigations and it was not thought necessary to hold any special inquiry into the matter. Consultations were taking place on legislation to guard against the accidental misuse of poisons.

Inspection of School Children.—Sir C. TREVELYAN, in reply to Mr. Somerville Hastings on December 11th, said that about six minutes was occupied on the average in the inspection of each child examined at routine medical inspection. Children discovered or suspected to be suffering from defects requiring more detailed investigation were referred for subsequent examination. The time then given to any particular child varied with the nature of the defect.

Votes in Brief

A provision that a suitable and efficient appliance for extinguishing fire must be carried is to be embodied in Ministry of Transport regulations for public service vehicles.

Cases of encephalitis lethargica notified in the administrative county of Lindsey (excluding the county boroughs of Grimsby and Lincoln) were 5 in 1928, 10 in 1929, and 6 up to the end of November, 1930. The local courts of the districts concerned are receiving the attention of the medical staff of the Ministry of Health.

Universities and Colleges.

UNIVERSITY OF LONDON

The following candidates have been approved at the examinations indicated:

THIRD M.B., B.S.—*M. P. Ellis, †I. V. Emmanuel, *Beatrice M. Joy, †G. I. Jones, M. Kraemer, †D. W. C. Northfield (University medal), A. W. M. Rook, †J. J. Barnard, †F. G. L. Barnes, J. N. Rhodes, W. L. M. Bibby, †G. Bowen, W. J. R. Branch, Dora I. Brockbank, †J. Campbell, W. H. I. Cant, †A. G. Carmichael, Rona I. Channing, A. Clark, †J. Claxton, †S. Cliff, W. D. Coltart, T. V. Cooper, Catherine R. Crane, †J. J. Croot, Marian J. Cunnick, Catherine Day, C. J. Dolman, D. G. Evans, †D. S. How, Beryl M. Furlong, Kamala Ghosh, Olive N. Grant, Mary W. Hamilton, Flora Hargreaves, Lettice I. Harrison, K. W. D. Hartley, Honor I. C. Harvey, A. S. Hatch, Katherine M. Holdcroft, †A. Hicks, R. J. Holmes, †I. B. Jackson, H. B. Jackson, †K. Jones, †F. J. King, G. C. Knight, H. J. Knight, Nellie I. Lanchman, †E. J. M. Laurent, †W. Lazarus, A. Levy, Annie M. McGrath, Joyce MacInnes, †A. H. M. McMullan, Moyra I. Macnaughton-Jones, Eileen M. Massey, †Elizabeth T. Mew, †R. Murray, †A. M. Nussbrecher, †A. C. Rice, R. S. Rick, †H. T. Robb-Smith, †C. F. Scott, Viola R. Sharp, Dorothy A. Sharpe, N. I. Sheppard, Ivorell M. Shipsey, C. K. Simpson, Ella Slater, D. Stanley-Jones, H. H. Stedman, †J. H. Stevenson, T. S. Stone, †G. Thomas, C. J. Thurlar, †S. Vere, the I.C.S. Well's, A. S. Whitfield, †R. Williams, Maureen D. Willmott, Frank H. Wilson.*

* Distinguished in medicine. † Distinguished in forensic medicine.
‡ Distinguished in surgery. § Distinguished in midwifery.

UNIVERSITY OF DUBLIN

TRINITY COLLEGE

AT the first winter commencements held on December 11th, the following degrees and licence were conferred:

M.D.—J. A. Bennet, C. Carlton, M. Gerber, D. A. Latham.
M.B., B.Ch., B.A.O.—G. Caldwell, T. H. Dockrell, H. H. G. Dorman, J. S. Duthie, G. I. Eunis, J. P. Fitzgerald, N. A. Kinnear, H. S. North, W. A. Robinson, J. B. Scott, Kathleen A. Wilson.
LIC. MID. SURG. AND OBSTET.—D. J. O'Flynn.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

AN ordinary meeting of the Council of the Royal College of Surgeons of England was held on December 11th, when the President, Lord Moynihan, was in the chair.

Fellowship

Diplomas of Fellowship were granted to the following successful candidates:

Gladys M. Sanders, J. M. Clarke, W. G. S. Brown, Annie Ichaimuthu, J. H. Saint, R. C. Tatham, N. W. Bolton, J. C. Ross, W. S. Chapman, R. Markham, B. R. Sworn, R. H. Metcalfe, D. G. Bown, F. H. V. Walker, A. M. P. N. Ray, K. S. Pilcher, W. Hynes, J. T. Chesterman, M. R. Ernst, J. N. Wardle, H. Yousri, M. D. Patel, J. R. Peacock, J. J. Gunner, N. B. Barrett, A. C. Fisher, W. J. Tucker, H. S. Taylor, Young, C. J. Corrigan, A. D. Everett, J. W. Holdsworth, R. Purvis, T. J. Millin, J. R. Stansfield, F. J. D'Arcy, S. G. Davidson, D. J. Fitzpatrick, J. C. B. Jones, T. J. Kemble, K. Lumsden, J. G. MacMahon, N. St. C. Mulhearn, L. R. Oliver, K. C. T. Fawle, C. A. M. Renou, V. N. Shirodkar, G. K. A. Syme, J. Taliat, S. A. M. C. Thompson.

Membership

Diplomas of Membership were granted to the following candidates, who had complied with the regulations: Marjorie Low, Marjorie Lunn, Thelwyn Newham, D. Ockman.

The Licence in Dental Surgery was granted to Poudicherry Somasunder, M.R.C.S.

Court of Examiners

The following were elected members of the Court of Examiners: Russell John Howard (re-elected), surgeon, London Hospital; L. C. Hughes, assistant surgeon, Guy's Hospital; Lionel L. C. Norbury, surgeon, Royal Free Hospital.

Primary Fellowship Examination in Canada

It was decided, on the request of the Canadian Medical Association, to hold a Primary Examination for the Fellowship in Canada next year, subject to satisfactory arrangements being made.

The thanks of the Council were given to Sir Frederic Hallett for his revised catalogue of portraits and busts of the College with short biographical notices and illustrations. Copies may be obtained from the Secretary, price 3s. cloth, 2s. 6d. boards.

Medical News.

THE Royal College of Physicians of London will be closed from Wednesday, December 24th, until Wednesday, December 31st, both days inclusive

THE Royal Society of Medicine will hold its next reception at 1, Wimpole Street W 1 on Wednesday, January 21st The president and Mrs Watts Eden will receive Fellows and their guests at 8 30 p m and at 9 15 p m Dr Arnold Chaplin will give an address entitled Great figures in history or misconceptions removed " Various objects of interest will be exhibited in the library Admission will be by ticket only, applications for which should be addressed to the secretary

AT a meeting of the Society for the Study of Inebriety to be held in the rooms of the Medical Society of London, 11 Chandos Street, Cavendish Square W, on Tuesday, January 13th, 1931 at 4 p m the Rev Courtenay C Weeks M R C S L R C P (editor of the *National Temperance Quarterly and Medical Review*) will open a discussion on Alcoholic indulgence in relation to motor transport " Members and associates may introduce visitors

THE London Jewish Hospital Medical Society (Stepney Green, E 1) has arranged two symposiums for the ensuing session The first, on February 12th 1931, on "The trend of medical practice will be opened by Mr Somerville Hastings The second on April 9th on "Modern advances in brain medicine and surgery," will be opened by Dr Gordon Holmes and Mr Julian Taylor

H H PRINCESS HELENA VICTORIA has promised to attend the annual children s festival of Dr Barnardo s Homes, to be held in the Royal Albert Hall on the afternoon of Saturday, January 17th, 1931

THE second International Congress and Exhibition of Sanitary Engineering and Municipal Hygiene will take place from April 20th to 26th, 1931 in Milan, under the patronage of the King of Italy Full particulars may be had by applying to the Secretary General of the Congress, 17 Piazza del Duomo, Milan Italy

THE Minister of Health has issued a Memorandum (131 c/T) containing an analysis of the work done during 1929 under the schemes of local authorities for the treatment of tuberculosis, the information having been supplied by returns furnished in accordance with Memorandum 37/T There has been a steady increase in the proportion of the total tuberculous population which is dealt with by these local authorities, and a continued fall in the proportion of undiagnosed cases on the dispensary registers more examinations of sputa are being performed The present Memorandum is intended to assist metropolitan borough councils in judging whether their schemes for the dispensary treatment of tuberculosis need any revision Four circulars—namely 1154 (a) (b), (c), and (d)—have also been issued by the Ministry relating to the returns to be made by local authorities in respect of maternity and child welfare, tuberculosis, and venereal diseases The Minister desires to know the number of cases of tuberculosis previously returned as cured which have relapsed, or shown indications of so doing He also wishes to know the total amount of accommodation available on December 31st in England and Wales for the residential treatment of tuberculosis at approved institutions forms have been designed for completion by local authorities and return to the Ministry not later than February 28th 1931 Other forms have similarly been issued in the case of institutions approved for the treatment of venereal diseases

THE welfare of African children will be discussed at an international congress to be held under the auspices of the Save the Children Union in Geneva in 1931, with special reference to infantile mortality, child labour and education, and child marriage

THE twenty first French Congress of Medicine will be held at Liege in 1931 under the presidency of Professor de Beco, when the subjects for discussion will be hyperthyroid states, metabolism of calcium and the treatment of non diabetic conditions by insulin

THE second International Hospital Congress will be held at Vienna from June 8th to 13th 1931 when the following papers among others will be read the cost of hospitals by Dr Distel of Hamburg the role of the hospital nurse by Mlle Pelmann of Geneva hospital terminology by Dr Wirth of Frankfurt hospital legislation by Mr Harper of Wolverhampton, out patient departments by Dr Corwin of New York the patient s diet by Professor Van Noorden of Vienna and the role of neurology and psychiatry in the general hospital, by Dr Alter of Dusseldorf.

THE Royal Institute of Public Health will hold its congress in Frankfurt next year from Tuesday, May 19th, to Sunday, May 24th The scientific work will be conducted in six sections—namely, State medicine and municipal hygiene, architecture housing, and town planning, industrial hygiene, women and children and the public health, tuberculosis, and pathology, bacteriology and biochemistry Visits will be paid to places of interest in Frankfurt, and the chief spas and health resorts of the Rhine including Wiesbaden, Homburg, Nauheim Kreuznach, and Münster am Stein, one day will be spent in an excursion to the university and town of Heidelberg Further information may be obtained from Dr T N Kelynack honorary secretary of the congress, 37, Russell Square, W C 1

THE November issue of the *Medical Women's Federation News Letter* includes among other articles an account by Dame Janet Campbell of her impressions of maternity and child welfare in Australia, an analysis of the interim report of the Departmental Committee on Maternal Mortality and Morbidity by Mrs Frances Iven Knowles, and obituary notices of Dame Mary Scharlieb

THE last issue of the *Fight Against Disease*, the quarterly journal of the Research Defence Society includes notes on the R S P C A and antivivisection, on asthma research, and on antivivisection in the war It is published for the Society by Macmillan and Co Ltd, St Martin s Street, W C 2

THE KING has appointed Dr Cyril Hartley Durrant, chief medical officer, St Kitts Nevis Medical Service, to be an *official member of the Executive Council of the Presidency of* St Christopher and Nevis for a further period

THE Röntgen Society and the Rhine Medical Society have conjointly decided to erect a monument to Röntgen at Lennep, near Düsseldorf, where he was born on March 27th, 1845

DURING the last five years there has been a gradual increase in the incidence of cerebro-spinal fever in the United States as is shown by the following figures 1925 1,859 cases 1926 2,226 cases, 1927, 3,204 cases, 1928, 5 781 cases, and 1929, 9 650 cases

Letters, Notes, and Answers.

QUERIES AND ANSWERS

Malaria and Blackwater Fever

DR C J PATEL (Kampala Uganda) writes Is there any preparation containing no quinine which can lower the temperature in blackwater fever and can destroy malarial parasites? I have had experience of 38 cases and I find quinine does harm I have seen the condition getting worse after small—say 1 grain—doses of quinine When a patient becomes comatose either in blackwater fever or in malaria what treatment should be adopted? I have tried saline per rectum and glucose intravenously but the result was not satisfactory and two patients died that way in coma How can the onset of coma be prevented and what are the signs which indicate that coma is threatening?

'Warbles' in Man

"T L M" writes "I have just had a most unusual case A boy of 5 was brought to me with the history that he had had within the last few days two itchy and painful swellings, one just above the right ear and one over the left shoulder blade The mother had squeezed them and had ejected two large white maggots one of which was brought to me for examination The swellings are large and pale, but not much raised, the one on the shoulder measuring 2½ in by 1 in On each is a small clean puncture, which admits a probe to a distance of about an inch Serum can be expressed on squeezing There is a history of a bruise on the head from a cow's horn but there is no indication of injury to the shoulder and no sign of external abrasion anywhere likely to be infected by flies, and, in any case, this is not the fly season The child is well nourished, strong, and healthy in every way, the parents are small farmers and he is constantly in contact with cows, horses and farm stock generally The maggot brought to me is pure white, about half an inch long, and appears to have eight segments I believe there is a common disease in cattle and deer due to fly, known locally as warbles, in which lumps appear containing maggots, but I have never heard or read of a similar case in man Can any reader state what larva this is likely to be, what was the probable method of infection and what is the best treatment to get rid of any further manifestations?

Pruritus with Jaundice

"W T T A" asks for any suggestions which would help him to alleviate an intolerable pruritus arising from a progressive jaundice due to carcinoma of the head of the pancreas in a woman aged 60 All the usual methods of treatment have been tried, but without success

Natural Labour after Caesarean Section

DAME LOUISE MCILROY writes In reply to the query published on November 22nd (p 891), six cases of spontaneous or forceps deliveries following previous Caesarean section were published from the Royal Free Hospital Obstetrical Unit by Dr Margaret Salmond, senior assistant, in the *Lancet*, October 15th, 1927 In all these cases the uterus stood the strain of labour perfectly In one two previous sections had been performed, and in three forceps were used as the second stage was prolonged Since the publication of this paper three others have been delivered spontaneously Taking the nine cases, the reasons for performing Caesarean section were central placenta praevia in three brow presentation in one, prolapsed cord in one asymmetrical pelvis in one toxaemia in two disproportion in one, and syphilitic granulomata of the vulva in another All the Caesarean operations were performed in the Royal Free Hospital, with the exception of the last two cases The method of suturing of the uterus in most cases is four layers the superficial row inverts the scar, so that adhesions are less likely to occur

Income Tax.

Obsolescence Allowance

"G W bought a car in 1926 for £3-0 He did not claim wear and tear allowance for the two years 1926-27 and 1927-28 but for the two subsequent years claimed and received allowances amounting to £66 in all In April, 1930 the car was sold for £75 and replaced by one costing £171 What is the correct amount of the obsolescence allowance?

*** The loss on the old car is, of course £330—£75=£255, less the sum of £66 already allowed—that is £189—but only £171 can be claimed as obsolescence The matter is governed by Rule 7, applying to Cases I and II, Schedule D which provides for the allowance of so much of any amount expended in that year in replacing any machinery as is equivalent, etc It will be seen that the amount expended is the maximum amount allowable

Agency Fees

A S explains that he has been refused the allowance of about £20 paid in agency fees over the two years 1928-29 and 1929-30

*** We are of opinion that a medical practitioner who exercises his vocation by doing locumtenent work or by taking *short term* employment as an assistant should be assessed as continuously employed, and not separately as in respect of the earnings of a number of separate employments If that is done—and that appears to be the usual course—the agency fees are, in our opinion, deductible as necessarily incurred in carrying on the profession in that particular manner

LETTERS, NOTES, ETC

Enlargement of the Thymus in Mumps

DR J D ROLLESTON (London S W 6) writes Dr E Esquivel, referring to this complication of mumps (see *Epitome*, December 6th para 560) expressed the view that it had not been described previously It was observed however, by the late Dr Joseph Sailer of Philadelphia during an epidemic of mumps in a military camp in the winter of 1917-18, and was reported by him in *Contributions to Medical and Biological Research* dedicated to *Sir William Osler*, 1919, vol ii p 1172

Robert Liston

DR F WILLIAM COCK (Appledore, Ashford, Kent) writes I have recently published remarks on Syme's amputation May I add an antiquary's note? When I was dresser, circa 1890 to Christopher Heath, at University College Hospital, it fell to my lot to attend to an old fellow who had had a Syme's done for him by Robert Liston He told me that it was the last operation Liston had performed, somewhere in the early summer of 1847 I removed a small sequestrum from the flat end of the tibia and though an old man, the patient healed quickly I asked him what sort of a man Liston was, he said a big, handsome man very bald He also added that he used a good deal of forcible language, as indeed all pre anaesthetic surgeons did The next patient to this one was a cabman with a stricture, who made a considerable outcry when Liston passed a largish silver catheter on him All right, my man, you needn't shout so much, you'll soon be able to drive your cab through this A little on the rough side, Sir, perhaps, but for all that Liston was one of the kindest men going and always ready to help the poor and penniless I wonder if there is any surgeon nowadays who would have 500 students and medical men follow his funeral, as was done when Liston died

Mercurochrome

DR CECIL L FOIDI (Oxton, Birkenhead) writes Mr E P Chambers's article on the treatment of ocular diseases with mercurochrome (December 13th, p 992) interests me very much I have generally used a 2 per cent solution of mercurochrome in a great variety of conditions, always as an antiseptic for the skin in the place of iodine for varicose ulcers, septic conditions dermatitis of various forms, pruritus and conjunctivitis both acute and chronic, and blepharitis, in fact, I consider mercurochrome one of the most useful drugs we have at our disposal

A Pregnancy Record

"I T S" writes I think the following case, if not a record is very close to it On January 2nd 1930 at 3 a m, Mrs X, a two para, gave birth to a baby girl but on account of retracted nipples the child did not suckle On February 6th Mrs X menstruated again and on November 13th, at 3 30 p m she gave birth to a full term 7½ lb baby boy (ten months and fifteen days) After twenty two years' experience, part of that time as interne at a maternity hospital, I offer this as a record

Puerperal Infection and Sanitation

SURGEON CAPTAIN A W B LAVERS, R N (ret) (Thorpe, Norwich) writes I have for some time thought that the high maternity death rate might be due to infection during pregnancy from sewer gas escaping up through the trap in the ordinary water closet The figures in the Interim Report of the Departmental Committee on Maternal Mortality do not negative this view According to these statistics America, prominent for perfect plumbing, has a mortality of 8 3 per 1,000, in France, notorious for poor domestic sanitation the death rate is 2 5 Great Britain holds an intermediate position with a mortality of 4 3 Apparently, the better the sanitation the higher the maternal mortality I ailing some other explanation I consider the water closet to be suspect It would be interesting in this country to compare the figures from an urban district having a perfect water carriage system with those of some rural area where the earth closet is still in general use

Lyle and De Souza's "Physiology"

MR HUMPHREY MILFORD writes In our full page advertisement of Oxford Medical Publications which appeared on page II of your issue dated December 6th, we regret that by an oversight the authorship of *A Manual of Physiology for Students and Practitioners* (third edition) was attributed solely to Dr H Willoughby Lyle It should be noted that, as in previous editions, the book was the result of the collaboration of that author with Dr David de Souza May we ask the courtesy of your columns to rectify the omission?

Second hand Cars

"BITTEN" writes I wish to warn my colleagues of the risks they run in buying from anyone unless personally known I bought a second hand car in 1928, a year old saloon model, of a well known make, having run a car of the same make for five years previously The period of the makers' guarantee had not expired The agent who sold me the car gave me a written statement taking over the makers' guarantee I had the car for about a year, during which time it cost about £80 in repairs and breakdown, and I sold it ultimately for £200 less than I paid for it No one should buy a second hand car without seeking expert advice from the A A, or some equally reliable source

Vacancies

NOTIFICATIONS of offices vacant in universities, medical colleges and of vacant resident and other appointments at hospitals will be found at pages 43, 44, 45, 46 47, 50, and 51 of our advertisement columns and advertisements as to partnerships, assistantships, and locumtenencies at pages 48, 49, and 50

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 268

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

539 Diagnosis of Arterio sclerosis

DIGITAL pressure on the point of division of the common carotid artery (bulbus or sinus caroticus) was shown by Czermak to cause a slowing of the heart beat, an effect which, according to later investigators, is due to direct stimulation of the carotid bulb, the afferent path being the descending branch of the glosso-pharyngeal nerve J HOCHSINGER (*Med Welt*, October 11th 1930 p 1462) has made clinical use of this reflex and tabulates his results in 1,500 cases of heart disease The test is best applied with the patient in the prone position, since giddiness is thus avoided The thumb is placed on the neck at the level of the upper border of the thyroid cartilage in front of the sterno mastoid and the tips of the other fingers are curved round the hinder edge of this muscle serving to palpate the carotid pulse The other hand may feel the radial pulse The carotid bulb is then pressed against the vertebral column with the thumb In all the author s cases the test was applied on the right side The application of pressure may be followed simply by a slowing of the pulse (weak positive), or by a dropping of one or more beats (strong positive) In one case as many as twenty beats were dropped Positive results were obtained most often in cases showing arterio-sclerotic changes, and were found to increase with age after 50 years Men were more frequently positive than women The electrocardiogram in strongly positive cases showed sometimes a small and sometimes a negative, T wave This result agrees with the experiments of Braun and Sammet, who obtained similar electrocardiographic pictures after ligature of a small branch of the coronary artery in cats The test can be used to distinguish true angina pectoris from vasomotor angina and coronary sclerosis from functional cardiac disturbances It is valuable also in prognosis, which is grave when the results are strongly positive

540 Nervous Sequels of Varicella.

LAIGNEL-LAVASTINE A. MIGET, and S CONSTANTINESCU (*Bull et Mém Soc Méd des Hop de Paris*, October 20th 1930, p 1448) record the case of a lad, aged 18, who while convalescing from an apparently mild attack of varicella developed symptoms of meningitis with convulsions and died in five days Post mortem examination of the brain and meninges confirmed the diagnosis of purulent meningitis with a cortical reaction Tuberculous meningitis could be excluded by the negative results of bacteriological examination and the inoculation of guinea pigs Meningeal reactions are frequent in varicella but this is believed to be the first case recorded in which meningitis occurring in convalescence from varicella has ended fatally

541 E TRAMER (*Med Klinik* October 24th, 1930 p 1598) reports two cases of diseases of the central nervous system following varicella in a boy aged 7 and a girl aged 3 years Both attacks occurred at the same time In one instance the symptoms were those of cerebellar encephalitis, and in the other of poliomyelitis Both patients, however, completely recovered in a relatively short space of time

542. Etiology of Juvenile Erythema Nodosum.

VARIOUS etiological factors have been suggested in erythema nodosum According to LL. B DICKEY (*Amer Journ Med Sci* October 1930, p 489) ample evidence is obtainable from study of the literature that the disease may either be caused by or be associated with conditions other than tuberculosis In the great majority of cases in children, however it is associated with a tuberculous infection and most of the infections are initial and recent The etiological role of tuberculosis becomes less constant with increasing age Most children who have erythema nodosum exhibit marked hypersensitiveness to tuberculin given intracutaneously This hypersensitiveness may possibly be influenced by other conditions such as asthma, vaccinia, and measles In addition to the tuberculous infection In many cases of erythema nodosum in children epituberculous lesions in the pulmonary parenchyma can be demonstrated by radiograms of the chest The lesions of the dermatitis the epituberculous lesions and the positive skin tuberculin reactions are similar histologically The disease is observed more frequently in females In a series of nine cases here recorded three occurred in boys whose ages ranged from 2½ to 14 years, and six in girls aged from 3 to 12 years None of these cases was known to develop a very active pulmonary tuberculosis Dickey asserts that in children under the age of 12 years the presence of erythema nodosum should be considered as indicative of recently acquired tuberculous infection and treatment of the initial infection should be started Proper attention paid the latter condition justifies a favourable prognosis as far as the tuberculosis is concerned

543. Fulminating Ascites.

E MAY and J STÉHELIN (*Bull et Mem Soc Méd des Hop de Paris* October 27th 1930 p 1499) report an early case of cirrhosis of the liver in which sudden ascites developed, copious enough to need urgent paracentesis On admission the patient gave a history of occasional slight oedema of the ankles and of abdominal distension, the liver margin was two fingerbreadths below the costal arch, and there was a slight amount of ascites No jaundice was present and no collateral veins were seen The lungs and heart were normal, and no sugar or albumin was found in the urine After eight days resting and dieting all these symptoms disappeared A week later the patient had slight rigors and diarrhoea, which persisted for a few days after this ascites suddenly developed, and 19½ ounces of fluid were drawn off to relieve the distress but he became steadily worse and died twelve days later from hepatic insufficiency The authors remark that the interest of the case lies in the sudden onset of ascites in a man suffering from the early stage of cirrhosis the ascites having been apparently provoked by a febrile toxic attack which could not be dealt with by a liver already diseased. Examination of the ascitic fluid showed a large preponderance of polynuclear cells, but a poor proportion of albumin, suggesting transudation rather than inflammation Since the onset of the ascites was too acute to admit of a mechanical explanation the authors suggest that the condition may have been attributable to some change in the humoral pathogeny, such as modification of the osmotic pressure of the proteins Postulating humoral theory renders the occasional recovery of some ascitic patients easier to understand than a purely mechanical theory, and it is suggested that if there are humoral changes favouring the development of ascites there may be also changes acting reversely and antagonistic to the pouring out of fluid

Surgery.

544. Fractures of the Acetabulum

W R CUBBINS, A H CONLEY and J J CALLAHA. (*Surg, Gynecol and Obstet*, September 1930, p 387) state that owing to the increasing incidence of automobile and aeroplane accidents, fractures in and around the acetabulum are becoming much more common. These fractures are classified as follows fractures of the rim fractures of one or two of the three bones of which the acetabulum is formed perforating fractures and fractures involving all the component bones. Concerning their etiology, the theory is advanced that fractures of the various parts of the acetabulum are the result of deviations in the position of the trochanter major With the exception of fractures of the rim, trauma to adjacent structures is a very important complication The iliac veins and arteries are commonly injured, with associated extensive haemorrhages that are frequently fatal The obturator, femoral, and sciatic nerves are often involved by lacerations and pressure The rectum and small intestines may be perforated. The bladder is frequently injured and great extravasations of urine are common The symptoms depend on the seat and extent of the fractures, and fall into three groups those in relation to the limb and its function (length and mobility), those in relation to the abdomen (tenderness and rigidity), and those in relation to the genito-urinary tract and rectum (blood in the urine and urethral injuries) The prognosis varies with the extent of the injuries to the large blood vessels and hollow viscera, shock and haemorrhage are the chief factors in prognosis. Treatment must first be directed to the emergencies such as repairing blood vessels and perforated viscera Rim fractures should be operated upon early The fragment should be replaced as normally as possible and be held in place by suitable means In fractures characterized by perforation or fragmentation, attempts at reduction should be made as soon as possible after the injury the degree of damage must be precisely ascertained before strenuous efforts at reduction are made In true perforations the head is sometimes

locked In such cases an incision parallel to and above Poupart's ligament should be made, the tissues being pushed away and the restraining fragments unlocked from the head and neck of the femur The head can then be forced out and held out by traction while the fragments are replaced and the wound is closed All cases need both longitudinal and lateral traction, methods of obtaining these are described Traction should be maintained for at least six weeks, and no weight should be borne on the limb for four to six months The patient should use crutches with a minimum of weight on the extremity for four months, the weight carrying should be gradually increased as the limb becomes stronger

545 Orthopaedic Treatment of Chronic Arthritis

SUMMARIZING the treatment of chronic arthritis, G A WILLIAMSON (*Minnesota Med*, October, 1930, p 708) deals mainly with its orthopaedic aspect, and defines two chief types, the proliferative and the degenerative In both of these search should be made for focal infection in the teeth and tonsils, and the morbid condition be thoroughly eliminated if present Postural defects should be remedied by supports and supervised exercise General measures such as rest and dieting should be instituted The abnormally low basal metabolic rate and lessened sugar tolerance which are present in many cases should be treated, the former with Lugol's solution or thyroid substance, the latter by a low carbohydrate diet Sodium salicylate induces the maximum relief of pain, though any drug that gives comfort may be administered Pain may also be alleviated by heat applied either generally in cabinets or cradle baths, or locally as by baking or diathermy In a definite percentage of cases relief of pain, subsidence of articular swelling with increased power of motion, and a general improvement follow the administration of triple typhoid vaccine to produce a foreign protein reaction The prevention of deformities is of prime importance, and splints are advocated, these and the correct positions in which the limbs should be immobilized are enumerated Too prolonged fixation of joints is harmful, since it produces ankylosis With the subsidence of pain and tenderness the joints should be baked and moved gently, both actively and passively Among surgical measures synovectomy and the extraction of loose bodies gives marked relief The former acts by removing joint exudate and infected tissue, and allows improvement in general metabolism owing to the early resumption of active exercise The question whether a movable joint or a fixed one in good functioning position is preferable must be decided for each individual case Operations for correcting deformities (osteotomy) and for producing movement in ankylosed joints (arthroplasty) are briefly discussed Reference is made to the sympathetic ganglionectomy of Rowntree and Adson (see *Epitome*, October 25th, para 371), which has proved of benefit in properly selected cases

546 Sequels in Cerebral Surgery

T DE MARTEL (*Presse Méd*, October 25th, 1930, p 1449) states that only one syndrome marks the terminal post operative sequels of cerebral and cerebellar tumours, this is constantly the same, and is characterized by hyperpyrexia, coma, and hypertension of the cerebro spinal fluid The circulation of the latter through the brain, as defined by Cushing, Dandy, and many other authorities, is described, and also three ways in which the hypertension is produced Every tumour causing an obstruction to the flow of the fluid from the ventricles to the lower cerebellar sinus brings about a dilatation of these cavities with consequent hypertension A secondary factor in this dilatation, which is slower in effect, is the escape of a portion of the brain through the occipital foramen, thus forming a cone of pressure The parts concerned are the lower portion of the bulb, the cerebellar amygdala, and the portions forming the walls of the lower half of the fourth ventricle A third cause of intraventricular hypertension comes into operation when the fluid accumulates in the cavities, but for some unknown reason is not resolved in the perivascular spaces and Pacchionian corpuscles The avenues of discharge from the ventricles may also be blocked by cellular debris resulting from the operation The author believes that the constancy of the symptoms is due to involvement of the same centres, and that the hypertension *acting on the centres in the third and fourth* ventricles provokes the coma, hyperpyrexia, and respiratory complications A case is cited which indicates the effect of even slight operative traumatism on the secretion of the cerebro spinal fluid, and the action of intraventricular hypertension on the centres named All treatment should be directed along these lines, two chief methods are described One which is related to the hyperpyrexia consists in cooling by cold applications, wet sheets, or by continuous intestinal irrigations of cold water The other, directed against the hypertension, comprises lumbar or the more preferable occipito atloidian punctures with a marked withdrawal of bloody fluid. If the hypertension persists, ventricular puncture should be performed Intravenous injections of hypertonic (15 per cent) solution of magnesium sulphate should be associated with the punctures These, by osmosis, diminish the amount of the fluid and the cerebral oedema This measure must be cautiously used, and the injections be given slowly During these procedures the patient should be in the Trendelenburg position this aids in the removal of a possible cone of pressure A low blood pressure (a bad prognostic sign) is best treated by injections of adrenaline and hyperphysin, the author gives these at the commencement of treatment as a prophylactic measure Extreme post operative care must be paid to cerebral cases, the rectal temperature should be taken hourly, and any untoward symptom be carefully noted

Therapeutics.

547 The Administration of Iron

SINCE many mixtures containing iron are very unpleasant, V J HENDERSON and T A SWEET (*Canadian Med Ass Journ* October, 1930, p 551) have made a study of combinations of iron salts and flavours, and present some simple, palatable recipes The following iron salts appear in the *Pharmacopoeia* the perchloride in the form of the solution and tincture, the sulphate, iron and quinine citrate, iron and potassium tartrate, and iron and ammonium citrate The perchloride preparations and the sulphate are intensely distasteful and difficult to disguise, they are not considered by Sweet, who regards them as no more effective than the other salts Iron and quinine citrate is disagreeably bitter and also very difficult to disguise, moreover, the quinine is no present in sufficient proportions to be of practical value Iron and potassium tartrate and iron and ammonium citrate have a marked metallic taste which no single flavouring syrup adequately masks The two best disguising syrups are the B P syrup of lemon and syrup of ginger, the best additions to mask the iron taste are simple syrup with compound tincture of lavender, liquid extract of liquorice, and compound tincture of cardamoms A useful prescription is ferri et ammonii cit 5 grains, tr lavandulae co 5 minims, and syrup 15 minims, in 1 oz of water Extract of liquorice or 15 minims of tr card co, may be substituted for the lavender Liquor arsenicalis may be added, if desired, in 2 minim doses If a laxative with the iron is required, sodium sulphate, which is not so bitter as magnesium sulphate, may be added in 20 grain amounts Of the bitters often given with iron only three are considered—quassia, calumba, and strychnine (nux vomica), of these, the last is the most, and calumba the least, agreeable, 5 minims of any of these tinctures may be given Bromides in 5 or 10 grain doses may be added to any of the mixtures described if the sodium salt is used The authors prefer the iron and quinine citrate for these mixtures, because it may be used in all cases, while iron and potassium tartrate may produce cloudiness or precipitation with bromides or liquorice The most palatable iron prescription is an old fashioned one containing liq ferri perchlor, liq potassae, ammon carb, tr limonis, sp myristicae, and syrup Liq arsenicalis, bromides, or sodium sulphate may be added to this, but not strychnine in any form In diabetics or children, saccharine gram 1/10, or 15 minims of glycerin, may replace the syrup in these prescriptions

548 Insulin in Morphine Addiction

M SAKEL (*Deut med Woch*, October 17th, 1930, p 1777) has treated fifteen cases of morphine addiction by large doses of insulin, and states that the serious and unpleasant withdrawal symptoms are almost abolished in this way The administration of morphine is stopped abruptly and on the first appearance of symptoms (unrest, diarrhoea, and vomiting) insulin is administered and continued for six to eight days in doses of up to 80 units daily according to the severity of the case At first glucose was given simultaneously, but this was found unnecessary, the insulin is more effective alone Small doses of barbituric acid are administered, since it has been shown that this drug considerably lessens the tendency to hypoglycaemic convulsions *in animals* Many of the patients were severely affected and had undergone in vain several previous courses of treatment It is claimed that by this method the somatic symptoms are combated promptly and effectively, the motor unrest and psychic disturbances are mild, the appetite remains, and the patients usually sleep without recourse to drugs Serious hypoglycaemic reactions hardly ever occurred, and no contra indications to the treatment have been found It is suggested that insulin acts by preventing disturbance of the equilibrium between the sympathetic and parasympathetic nervous systems.

549 **Insulin in Diabetic Coma.**

I I LEMANN (*Amer Journ Med Sci* August, 1930 p 266) reports the findings in the investigation of 47 cases of diabetic coma in support of Joslin's contention that the use of alkalis in this condition is unnecessary Of the 47 patients 5 died Six patients received small doses of alkali and of these 2 died one of whom received an insufficient amount of insulin Of the 41 cases receiving no alkali 3 died, 2 within two hours of admission to hospital, and the other possibly as the result of the administration of too little insulin (150 units in fifteen hours) Lemann maintains that insulin alone not only acts as a specific antidote to the ketone bodies, but also raises the CO_2 content of the blood, sometimes to the point of a definite alkalosis He concludes that whether the coma is to be regarded as due to the acidosis or to intoxication by the ketone bodies, insulin is sufficient alone to combat it

550 A F COBURN (ibid p 178) has also investigated cases of diabetic coma in which death occurred although insulin was administered in sufficient doses He finds that the most important factor in recovery is the excretion of the acetone bodies rather than their oxidation and he claims that ketonaemia may exist without ketonuria on account of a functional renal inefficiency This condition may progress to anuria, thus greatly increasing the risk to the patient The intravenous injection slowly of large amounts of hypertonic fluids containing glucose and alkali has been found to be the most valuable method of stimulating the excretion of the ketone bodies in correcting the anuria and overcoming circulatory renal collapse Recovery from coma depends largely on the rapidity with which the ketone bodies are excreted by the kidneys and the renal inefficiency is overcome

Ophthalmology

551 **Chancre of the Ciliary Margin.**

D M ARGÜELLO (*Rev Med Lat no Americana*, July–August, 1930, p 1429) who records a personal case, states that in Fournier's series of 1 124 extragenital chancres 849 were situated in the cephalic region and of these 21 were ocular chancres This localization was first described by Ricord in 1850 The ciliary margin, skin of the eyelids, and conjunctiva are attacked in the order named Ocular chancre is more frequent in the male than in the female It is observed at all ages, and even in the child at the breast Medical practitioners are specially liable to be affected The mode of contagion is often impossible to determine as in the author's case but it is most frequently the projection of particles of saliva on to the eye from the mouth of persons who have oral mucous tubercles Kissing is the next most frequent cause Sexual aberrations are also sometimes responsible Argüello's patient was a man aged 35 who developed an ulcer on the ciliary margin of the right lower lid accompanied by enlargement of the submaxillary and pre auricular glands On further examination a typical syphilitic roseola was found on the trunk and thighs The Wassermann reaction was positive, and disappearance of all the symptoms took place within a month under specific treatment

552. **Dental Infection and Diseases of the Eye.**

W F C STEINBÜGLER (*Arch of Ophthalmol.*, August 1930 p 220) remarks that the frequency of dental infection in eye disease reported by different observers ranges from 40 to 4 per cent The iris ciliary body and choroid are most frequently affected, acute iritis followed by cyclitis being usually due to a bad condition of the mouth, while a low grade chronic inflammation with no tendency to exudation is associated with apical infection in a clean mouth The commonest forms of infection are apical or peri apical infection (root granuloma) caries, and pyorrhoea alveolaris while the most dangerous forms are infections of the pulp pulpless teeth and apical abscesses since they are free from symptoms and hence are not suspected The transmission of infection from a tooth to the eye may be by the lymphatics perivascular lymph spaces perineural lymphatics, directly through the bone by way of the periosteum or by the blood stream Clinically the route is very variable These dental infections are most often associated with non haemolytic streptococci and less frequently with haemolytic strains pneumococci staphylococci and *Micrococcus catarrhalis* are rarely implicated Broth cultures from infected root tips injected into rabbits produced lesions of the joints kidney, endocardium myocardium brain eye, stomach and duodenum in that order of frequency With regard to the detection of dental infection *x* rays do not give very great help, since the incidence of infection is almost as high with negative as with positive skiagrams There is a wide divergence of opinion whether stock or autogenous vaccines give the best results some observers even concluding that since *the immunity to the streptococcus is so short lived, no great* results may be expected from this form of treatment A special type of lymphocyte is described which is always found when there is oral infection, but never when there is no such infection Up to 1 5 per cent. represents a normal blood count while above this a pathological condition of the mouth is present Clinically there is no ophthalmological picture indicative of dental infection In eye diseases elimination of oral sepsis should take precedence over preservation of the teeth

553 **Ocular Myiasis.**

C P SCHENCK (*Amer Journ of Ophthalmol* September, 1930, p 801) reports a rare case of ocular myiasis a disease due to the presence of fly larvae in or on the body It is most common in tropical countries where the larvae are found in sores and wounds on animals they have been found also in man. In May, 1928 a workman felt a foreign body hit his eye Wiping had no effect, and he had the eye examined. Six or eight hours later twenty five large larvae were removed from the conjunctival sac Eversion of the lower lid revealed what looked like a minute black dumb-bell progressing in jerky movements A curved toothless forceps proved best for *removing the larvae Two larvae were found beneath the* bulbar conjunctiva To avoid an incision, since the slightest haemorrhage would have obscured the larvae the curved iris forceps with blades separated was laid with the convex side against the conjunctiva and a mass of the latter including the larvae was drawn away from the sclera The conjunctiva and larvae were then touched with the red hot electro-cautery point, which destroyed both conjunctiva and parasite The patient's recovery was immediate

Obstetrics and Gynaecology.

554 **A Post-climacteric Symptom-Triad**

H C GRAM (*Ugeskrift for Laeger* October 23rd, 1930 p 993) groups as a post climacteric symptom-complex adipositas dolorosa hyperplesia and arthritis of the knees He believes that this association is very common, and that its onset development, and manifestations, subjective and objective are so uniform that it may be regarded as a nosological entity Each condition by itself is familiar to all practitioners and the possibility of a relationship between each of them and the menopause has frequently been assumed But hitherto each of these three has been studied separately and not in conjunction with the other two Gram's material consisted of 60 cases, examined personally and of a total of about 200 if all the cases on which he has had to adjudicate in connexion with health insurance are included The first characteristic of this group is its short expectation of life The causes of death are as a rule an acute infection such as influenza, bronchitis or pneumonia or failure of the heart. With regard to the frequency of the subjective manifestations among the 60, there were 47 who complained of vague rheumatic pains and 22 who had pain in the knees In as many as 53 cases such cardiac symptoms as functional dyspnoea or palpitation of the heart were reported Most of the patients were very fat and the average weight of the 60 was 11 st 10 lb Painful subcutaneous infiltrations were recorded in 48 cases, and tender areas of the skin in 50 there were only 6 cases in which neither of these symptoms was recorded. Even this small number could have been further reduced had the routine search for such symptoms been more thorough The average systolic blood pressure was 174 A control investigation of the systolic blood pressure of 30 women between the ages of 40 and 62 whose weight was normal, and who were otherwise presumed to be perfectly healthy, showed an average of only 133 mm of mercury In 53 cases the only joints affected were the knees In the remaining 7 some other joints were involved The basal metabolism was investigated in 20 cases and the average found to be 106 4 per cent. The age of onset of the menopause was recorded in 56 cases and the average age was 47 9 years A control investigation of 56 other women not showing this symptom-complex yielded the figure 48.2 as the age at which the menopause set in There would therefore seem to be nothing abnormal about the age at which the menopause appeared in the patients showing this symptom-complex. Among 54 patients the average duration between the menopause and the discovery of this symptom-complex in hospital was about eight years but his probably means merely that patients wait many years before coming to hospital with their complaints The average number of

confinements and abortions among these patients was 4 5, whereas the corresponding number was only 2 8 for the 60 controls, over the age of 45 not showing this symptom complex Numerous pregnancies would therefore seem to be a predisposing factor

555 Rapid Appearance of Chorion-epithelioma after Hydatidiform Mole

As an example of the strikingly rapid and insidious onset of chorion epithelioma after hydatidiform mole, J COLLI and J MONTAGNE (*Bull Soc d'Obstet et de Gynécol de Paris*, October, 1930, p 547) cite the case of a woman, aged 51, who after ten weeks' metrorrhagia expelled spontaneously a vesicular mole Four weeks later, in the absence of anaemia, uterine bleeding, and subjective signs of illness, the uterus, although mobile, was found to be enlarged to the size of the fist In view of the patient's age preventive hysterectomy was decided on, the operation proved unexpectedly difficult by reason of a neoplastic infiltration of the right broad ligament, which contained a hard enlarged gland The chorion epithelioma occupied a circular area in the right half of the uterus, suggesting the placental attachment Hysterectomy as a routine after hydatidiform mole has been recommended as a preventive measure by Neumann, *although only a small* percentage of hydatidiform moles are followed by chorion epithelioma, and in many normal pregnancy ensues The rapid appearance of the neoplasm in this case, and its distant extension without clinical signs, are taken to justify Neumann's advice, certainly in respect of women aged 50, and probably in those younger

556 W ROSENSTEIN (*Zentralbl f Gynäk*, October 18th, 1930, p 2652) describes a case in which a clinical diagnosis of chorion epithelioma was possible as soon as eight days after the operative removal of a hydatidiform mole The patient, a 3 para aged 24, had reported bleeding during the fourth month of pregnancy, repeated microscopic examinations of the mole showed typical characters with no hint of malignancy The diagnosis of chorion epithelioma was assured by the renewal of bleeding on the eighth day, and the detection at the same time of a metastasis on the posterior vaginal wall Microscopical appearances typical of chorion epithelioma were found in this metastasis, a neoplasm was found deeply infiltrating the myometrium As is the rule, lutein cysts were found in the ovaries The patient was quite well four months after operation, which was followed by the application of x rays

Pathology.

557 Asbestosis Bodies in the Sputum and Lungs

IN comparatively recent years the asbestos industry has progressed rapidly, and, consequently, asbestosis has become an important industrial disease K M LYNCH and W A SMITH (*Journ Amer Med Assoc*, August 30th, 1930, p 659) summarize the reports of previous writers and describe several cases of their own Asbestosis was formerly regarded as a form of silicosis, black particles of various shapes from 3 to 393 μ in length being found Recent researches have revealed *peculiar features* in asbestosis which are absent in ordinary silicosis In addition to pulmonary fibrosis, chronic bronchitis, tuberculosis, and anthracosis, asbestosis bodies have been present in all the recorded cases, their nature is uncertain, but it is suggested that they are asbestos fragments undergoing hydrolytic changes during absorption of silica in colloidal form In the four cases first recorded the lungs contained "golden yellow" segmented structures, having rounded ends, in those reported by the present authors similar bodies in large numbers were found in the lungs, bronchi, peribronchial lymph nodes, and venous thrombi In the lungs and lymph nodes there was much black granular pigment and a quantity of a yellow brown granular substance of the same colour as the asbestosis bodies Numerous mononuclear and polynuclear giant cell phagocytes were associated with them in the pulmonary alveoli, bronchi, and veins *The phagocytes* contained much black granular pigment General fibrosis was present The authors examined the sputum of asbestos workers, concentrated after *digestion in a 10 per cent NaOH solution* at about 176 F The first specimen was from a man who had active caseous tuberculosis and a moderate degree of pneumoconiosis He had worked with asbestos for ten years until one year before examination The sputum contained many tubercle bacilli and asbestosis bodies This confirmed the findings of other observers who employed concentrated antiformin and centrifugalized the precipitate Lynch and Smith found asbestosis bodies in the sputums of two other asbestos workers, but *failed to find them* in a third patient These bodies vary in size, colour, and form, but are usually similar in structure, in sputum they have a central transparent slightly green spicule, which may be an asbestos crystal On this are deposited nodules and fragments of homogeneous refractile substance varying in colour from shining yellow or greenish yellow to a deep mahogany These nodules occur usually at the extremities of the spicule, giving a clubbed or dumb bell appearance, the shaft is sometimes covered by a homogeneous non segmented deposit Asbestosis bodies are refractory to ordinary tissue and sputum stains but they may be stained on the slide by the "prussian blue" test, thus indicating a considerable iron content This may show that the asbestosis body originates from the iron constituent of asbestos but more probably the iron is of tissue origin derived from the blood

558 Leucin and Tyrosin in the Urine in Lung Tumours

H ASPERGER (*Wien Klin Woch*, October 16th, 1930, p 1281) has found these amino acids in the urine of three patients suffering from bronchial carcinoma They have also been detected in the urine in acute yellow atrophy of the liver and occasionally in severe catarrhal jaundice, and may be present in typhus, variola, pernicious anaemia, leukaemia and other diseases producing severe cachexia, and also in prolonged chloroform anæsthesia They are found normally in the bowel as a result of tryptic digestion of albumin, and their appearance in the urine is a grave sign, although not necessarily indicating a fatal termination of the disease The *first patient*, a man aged 47, had an apical pulmonary catarrh for six months, followed by intense thoracic pain and a severe dry cough, night sweats and rapid emaciation Repeated paracentesis yielded a constantly increasing exudate containing much albumin, and erythrocytes with 90 per cent lymphocytes The patient died from heart failure, and the necropsy revealed carcinoma of the left upper lobe, with pleurisy, many bony metastases tuberculosis at the apex of the right lung, anal fistula, and cystitis Six weeks before the patient's death leucin and tyrosin appeared in the urine The second patient, aged 57, had complained for two years of inflammation in the neck Six months before admission he had fever and stabbing pain in the chest on deep inspiration, and pleurisy was diagnosed, but later the condition was recognized as being bronchial carcinoma Leucin was found in the urine, and tyrosin appeared subsequently Asperger's third patient, a man aged 56, was diagnosed as having bronchial carcinoma with multiple metastases, a cerebral metastasis terminated his life Leucin was found in the urine in increasing quantity for one month before death, but the presence of tyrosin was doubtful The author cites a similar case reported by Risak, and refers to experiments by other authors indicating that leucin and tyrosin are found in pneumonic consolidation (grey hepatization) after incubation for three to five days, and also in defibrinated blood after autolysis It is concluded that necrosis of animal tissues produces these amino acids, probably by the action of a ferment contained in the leucocytes In addition to the previously mentioned diseases leucin and tyrosin have been found in sputum and in various pulmonary diseases such as fetid bronchitis, pulmonary abscess, bronchiectasis, and tuberculosis In one case of bronchial cancer which terminated in gangrene large quantities of leucin and tyrosin were found in the sputum

559 Bovine Tubercle Bacilli in Pulmonary Tuberculosis

A S GRIFFITH (*Journ Path and Bact*, October, 1930, p 1145) calls attention to the number of cases of pulmonary tuberculosis examined recently which have been found to be due to tubercle bacilli of the bovine type Before 1924 only four cases of bovine infection had been reported in Great Britain, since that date, however, seventeen patients have been discovered who were expectorating bovine tubercle bacilli With one exception these recent cases have all occurred in Scotland, and have been studied by Munro Taking all the figures together, 3 out of 327 patients in England, or 1 per cent, have been found to be infected with bovine bacilli, while in Scotland 18 out of 468 have been found, or approximately 4 5 per cent Clinical and post mortem investigations indicated that the majority of these patients had been infected by the alimentary tract, the portal of entry in the remainder was *doubtful The author discusses* the comparative rarity of ulcerative pulmonary tuberculosis as a sequel to alimentary tuberculosis of bovine origin He suggests that a dissemination of bovine bacilli in amounts sufficient to give rise to miliary tuberculosis of the lungs may invariably prove fatal, and secondly, that bovine pulmonary tuberculosis may be more frequent than it appears to be Owing to the fact, however, that the lesions in the lungs are of vascular origin, they are less liable to break down than those of respiratory origin, and consequently bovine bacilli rarely appear in the sputum

An IMPROVED and MODIFIED

Portable Traction Apparatus

An exceedingly efficient and convenient apparatus for putting up in plaster the lower limbs or trunk, also when applying bone plates or Parham and Martin's Bands to long bones of the lower extremity Provides the more essential movements of expensive and bulky Orthopaedic tables at a fraction of the cost.

Quickly adaptable for the following positions

Extension of whole lower limbs
Movements about hip joint
Abduction to any degree—
Hyperextension—Flexion—
Internal and External Rotation.
Flexion of knee joint
Inversion and Eversion of foot

SAVES BEDS IN HOSPITALS

A limb may now be put up in plaster, the patient sent home and transported for subsequent treatment by ambulance By thus freeing beds this new apparatus saves its cost many times over

Folds compactly for storage or transit in plywood case 35in × 15in × 11in

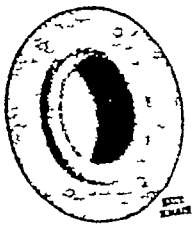
SALT'S COLOSTOMY BELT

with Sterilizable Rubber Cup

(Registered No. 749046)



This Belt is specially designed for cases where faeces are of a solid nature or the amount is small.

The special feature is the Cup which is made of moulded rubber in one piece.

It has no corners or crevices and therefore does not retain the odour

The advantages in this Belt are —

1 Detachable Cup sterilizable by boiling, repeatedly without deterioration
2 No crevices or metal fittings to hold faeces
3 Smell reduced to a minimum
4 Minimum of bulk
5 Cups easily and economically replaced

View of cup showing moulded rubber pad which fits snugly against the body

Side view of Cup. The Cup flange and circular pad are made as one moulding

PROVIDES HIGHLY SUCCESSFUL ORAL AND POSTAL COACHING FOR ALL MEDICAL EXAMINATIONS

Special Preparations for all Surgical Qualifications

F R C S ENGLAND (Primary & Final.) M C CANTAB M S LONDON

F R C S EDINBURGH

And all other Surgical Degrees and Diplomas.

The remarkable success of Students of the Medical Correspondence College at the higher Surgical Examinations is specially noteworthy

Both at the Primary and Final F R C S England the majority of our Students are successful at the first attempt and Candidates who have failed at these Examinations on several previous occasions get through without difficulty after going through our course

The Surgical Tutors of the College all hold either the M S Lond or F R C S England or both and are highly experienced teachers

The Postal Courses are throughout clear concise and up to date and the test questions are carefully selected from those set at previous Examinations so as to embrace all parts of the subject By working systematically through the Course the Student is brought up to the examination standard in the minimum time and much unnecessary reading is saved.

INDIAN MEDICAL SERVICE

Recruitment of European Officers.

Applications are invited from medical men for permanent commissions in H.M.'s Indian Medical Service. The terms offered include a gratuity of £1,000 on retirement after six years' service, or £2,500 after 12 years' service, together with free return passages, for those who no longer desire to remain in the Service. In other respects the terms will be as detailed below.

Candidates must be British subjects under 32 years of age at the time of application and must be registered under the Medical Acts in force in Great Britain and Northern Ireland.

CAREERS

The Indian Medical Service offers wide opportunities of medical experience including clinical preventive specialist and research work. At the beginning of his career an officer is employed on the military side which has medical charge of the Indian Army. Promotion is on a time scale up to the rank of Lieutenant Colonel and by selection to the ranks of Colonel and Major General. An officer may apply after one year's Indian service to have his name registered for transfer to the civil side from which appointments are made to Civil Surgeoncies which are established at the principal civil centres to provide for the medical needs of civil officials and for general medical administrative purposes to specialist (for example public health and bacteriological) services to research posts and to professorships at the Medical Schools.

PAY

The monthly rates of pay for European officers in the Service who have a non-Asiatic domicile are as follows:

Rank	Service in Rank	Basic Pay	Overseas Pay	Years of Total Service
1	2	3	4	
		Rs.	Rs.	
Lieut.	—	400	150	1st
			150	2nd
			150	3rd
Capt.	(i) During first 3 years service as Captain	600	150	4th
			£11	5th
	(ii) With more than 3 and less than 6 years service as Captain	700	£11	6th
			£11	7th
	(iii) With more than 6 years service as Captain	800	£11	8th
			£11	9th
			£11	10th
			£11	11th
			£30	12th
Major	(i) During first 3 years service as Major	900		
	(ii) With more than 3 and less than 6 years service as Major	1100		
	(iii) With more than 6 years service as Major	1250		
Lieut.-Col.	(i) Until completion of 9 years total service	1400	£30	13th
	(ii) During 13th and 17th years service	1800		14th and over
	(iii) After completion of 17 years total service	1600		
	(iv) When selected for increased pay	1800		

EXTRAS.—In addition to the above rates various allowances are admissible for a large number of special appointments on both the military and the civil side which may be held by members of the Indian Medical Service. Special high rates of pay are also attached to the numerous administrative appointments open to officers in both branches of the Service.

ANTEDATES IN COMMISSION

Any service rendered by an officer during the war as a medical or combatant officer or in a position usually filled by an officer may be counted as service for increments of pay promotion retirement and retired pay but not for gratuity.

One half of any service in the ranks during the war may be counted as service for retirement and retired pay only.

Candidates possessing certain higher medical qualifications may be granted an antedate of one year in their commissions. Past service in certain hospital appointment may also render candidates eligible for an antedate of one year. Persons holding or about to hold resident posts at recognized hospitals may be seconded in those posts for a period not exceeding one year. The maximum period of antedate secondment or antedate and secondment combined admissible under this paragraph is limited to one year.

OUTFIT ALLOWANCE

Officers on appointment will receive an outfit allowance of £50.

PRIVATE PRACTICE

With the exception of Administrative Officers military or civil and officers holding certain special appointments officers are not debarred from taking private practice so long as it does not interfere with their proper duties.

LEAVE

Leave can be taken at reasonable intervals and adequate rates of leave pay are provided. Extra leave (known as study leave) which may not exceed 12 months in all during an officer's service may be granted to officers desirous of pursuing special courses of study of a post graduate nature. During such leave study allowance at present fixed at the rate of 12s. a day in the United Kingdom £1 a day on the Continent of Europe and £1 10 a day in the United States of America is granted to an officer in addition to ordinary rate of leave pay.

PENSIONS

The rates of pension are as follows	Per annum £
After 17 years service for pension	400
18	430
19	460
20	500
21	540
22	580
23	620
24	660
25	700
26	750
27	800

These rates are subject to alteration on account of a rise or fall in the cost of living as compared with the year 1919 to an extent not exceeding 20 per cent. in all the revision being undertaken triennially. With effect from July 1st 1930 a reduction of 5½ per cent has been made on this account from the amounts shown.

There are additional pensions ranging from £65 to £350 per annum for officers who have held administrative appointments.

PASSAGES

An officer on appointment is provided with free passage to India. The wives and families of officers who are married prior to the date of the officers embarkation on first appointment will also be provided with free passage to India subject to the payment of messing charges.

Officers and their families are also eligible for passage concessions under which they are granted a certain number of return passages home at Government expense during their service.

INSTRUCTION PRIOR TO EMBARKATION

Officers are required to undergo courses of instruction at the Royal Army Medical College and at Aldershot lasting approximately six months prior to their embarkation for India on first appointment.

Full details regarding these appointments and forms of application may be obtained from the Under-Secretary of State for India, Military Department, India Office, London S.W.1. The Selection Committee will meet at the India Office early in January next and the selected candidates will be required to join a course of instruction commencing early in February 1931, prior to sailing for India in the Autumn of 1931. Applications should be submitted as soon as possible.

Powdered by the
COW & GATE
Improved
Roller Process

Peptalac REGD

THE NEW INSTANT PREDIGESTED FOOD

Predigestion of starch *and* milk is guaranteed and is effected under the most exact scientific conditions in our laboratories before powdering This means that when required for use it can be immediately and simply prepared by the *mere* addition of hot water The C & G Improved Roller Process is used ensuring retention of the full mineral and vitamin content with freedom from pathogenic organisms

PEPTALAC is indicated in all those cases where the powers of the digestive tract are insufficient to deal with that amount of food necessary for maintaining health—for nursing mothers with weak digestions, in ante- and post-operative surgical cases, in achlorhydria, peptic ulceration, cancer of the alimentary tract, in all forms of convalescence and in old age.

CITRONIN

A New and Effective Preparation for Alleviating Cough

CITRONIN is a beautifully clear, cherry-red liquid with an agreeable aromatic fruity odour It is not a "syrup"

The potassium guaiacol sulphonate in this preparation has a definite germicidal action and it possesses the advantage of not disturbing the digestion as other guaiacol salts do The sodium citrate and citric acid stimulate bronchial secretion and also aid in liquefying the secretions thus formed The action of ipecacuanha is well known, as is also that of ethylmorphine Cascara Evacuant has been incorporated for its eliminative and intestinal tonic effects

Bronchitis, subacute or chronic, suggests the use of Citronin, in which conditions it can be expected to loosen the dry cough within a short time For adults the dose of Citronin recommended is one or two teaspoonfuls at intervals of not less than three or four hours

Each fluid drachm of Citronin represents —

Potassium Guaiacol Sulphonate	1 grain
Sodium Citrate	2-1/2 grains
Citric Acid	1/2 grain
Cascara Evacuant	3/4 min
Fl Ext Ipecacuanha	3/8 min
Ethylmorphine Hydrochloride	1/32 grain

Supplied in bottles containing 4 ozs, 16 ozs and 80 ozs A sample will be supplied on request

CALCIUM-SANDOZ

$(C_6H_{11}O_7)_2\,Ca$

Unique Advantages:

1.—It is effective. It supplies the physiologically active calcium ion

2.—It shows distinct superiority in all modes of administration

ORALLY It is well absorbed It is easily administered and does not upset the digestive tract

INTRAVENOUSLY It is better tolerated than calcium chloride The acid-base factor is eliminated

INTRAMUSCULARLY It is painless and non-irritating It is the only calcium salt which can be so administered in adequate doses

3.—It enables physicians to adequately meet the requirements of any given case.

By VEIN, for acute need
By MUSCLE, to secure intense and prolonged action
By MOUTH, for prolonged administration, to meet an increased demand by the organism

4.—It is completely sufficient in itself as a therapeutic agent.

CALCIUM-SANDOZ is supplied in

Ampoules containing a 10% sterile solution for intravenous or intramuscular injection
5 c c size Boxes of 2 and 10 ampoules
10 c c size Boxes of 1, 5, and 20 ampoules

Powder for oral administration—Cartons of 2, 4, and 16 ounces

Tablets for oral administration—Each tablet contains 25 grains of calcium gluconate and is especially adapted for division into three parts Boxes of 30 and 150 tablets Cartons containing 12 boxes of 30 tablets

OUTSTANDING BOOKS OF 1930

TREATMENT IN GENERAL PRACTICE

By HARRY BECKMAN M.D., Professor of Pharmacology Marquette University Milwaukee Octavo of 899 pages. Cloth 45s net.

"This book or its equivalent should be in the hands of every physician and we have not yet come across its equivalent. —THE LANCET

SURGICAL DIAGNOSIS

Edited by EVARTS A. GRAHAM M.D. Bixby Professor of Surgery Washington University St. Louis Three octavo volumes totalling 2,750 pages with 1,275 illustrations and separate Desk Index Volume. Per set Cloth 150s net.

Altogether this work can be very heartily recommended since it presents the state of modern surgical knowledge in a very fair and unbiased manner it will especially appeal to those who believe that surgery is a science as well as an art. —BRITISH MEDICAL JOURNAL.

ORTHOPEDIC SURGERY

By WILLIS C. CAMPBELL, M.D., F.A.C.S. Professor of Orthopedic Surgery University of Tennessee Octavo of 705 pages with 507 illustrations Cloth 37s 6d net.

The book can be recommended with confidence to the general surgeon as well as to the specialist who is called upon to treat such affections It is nicely illustrated and many radiograms are reproduced The general production of the volume—binding print etc.—is excellent and we foretell for it every success —IRISH JOURNAL OF MEDICAL SCIENCE.

MAYO CLINIC PAPERS OF 1929

By W. J. & C. H. MAYO and their ASSOCIATES at the Mayo Clinic and the Mayo Foundation University of Minnesota. Octavo of 1197 pages with 279 illustrations Cloth 60s net.

"There could be no better mirror of the progress of surgical science than the Mayo Clinic volumes Each department of the Clinic keeps itself informed of what is being done elsewhere and every new suggestion is put to the test on a scale and with a thoroughness which cannot be matched in many clinics —THE LANCET

DISEASES OF THE SKIN

By GEORGE C. ANDREWS A.B., M.D., Associate Professor of Dermatology College of Physicians and Surgeons Columbia University Octavo of 1091 pages with 988 illustrations Cloth 50s net.

The whole volume is excellently got up and considering the amount of matter contained in it remains moderate in size and easy to handle We commend it with confidence both to general practitioners and specialists —BRITISH MEDICAL JOURNAL.

TEXT-BOOK OF HISTOLOGY

By ALEXANDER A. MAXIMOW late Professor of Anatomy University of Chicago Completed and edited by WILLIAM BLOOM, Assistant Professor of Anatomy University of Chicago Large octavo of 833 pages with 604 illustrations some in colours Cloth 40s net.

The book is one which can be recommended with confidence as a general work of reference for the more advanced student of this branch of study —BRITISH MEDICAL JOURNAL.

LEGAL MEDICINE & TOXICOLOGY

By RALPH W. WEBSTER, M.D., Ph.D., Clinical Professor of Medicine in Rush Medical College. Octavo of 862 pages illustrated. Cloth 37s. 6d. net.

In this new book Dr. Webster has sifted the important from the unimportant selected facts and expressed them clearly, and presented a concise work on legal medicine and toxicology for all conversant with the legal side of medicine or the medical side of law

TEXT-BOOK OF MEDICINE

Edited by RUSSELL L. CECIL, M.D., Assistant Professor of Clinical Medicine, Cornell Medical School. Octavo of 1,592 pages illustrated Second Edition. Reset. Cloth 40s. net.

This book maintains a very high level throughout its pages Great care has been taken with the dovetailing together of the various contributions into a compact whole and the book is a worthy production of the modern American school of medicine —THE LANCET

DEVELOPMENTAL ANATOMY

By LESLIE BRAINERD AREY Robert Laughlin Rea Professor of Anatomy Northwestern University Medical School Large octavo of 560 pages with 1037 illustrations on 532 figures New 2nd Edition. Cloth 27s. 6d net.

Professor Arey has published a text book which includes more post natal development than most other manuals of embryology The outline presented of the more important developmental changes manifested after birth is a very valuable addition Professor Arey is to be congratulated on the production of a text book of embryology which may be highly recommended and is likely to be used very widely —BRITISH MEDICAL JOURNAL.

MEDICAL BIOMETRY & STATISTICS

By RAYMOND PEARL, Professor of Biology School of Hygiene, Johns Hopkins University Octavo of 459 pages illustrated. Second Revised Edition. Cloth, 25s. net.

An interesting and useful book which will appeal to many others besides those for whom it is primarily intended" —JOURNAL OF THE INSTITUTE OF ACTUARIES.

W. B. SAUNDERS COMPANY Ltd., 9, Henrietta Street, LONDON, W.C.2

DISEASES OF THE HEART

THEIR DIAGNOSIS, PROGNOSIS, AND TREATMENT BY MODERN METHODS.

With chapters on the Ink Polygraph, Clinical Electro Cardiography, X-Ray Examination, and Anaesthesia in Relation to Cardio-Vascular Affections

By FREDERICK W PRICE, M D, F R S (Edin),

Senior Physician to the National Hospital for Diseases of the Heart Consulting Physician to the Royal Northern Hospital London
Demy 8vo Pp 534 With 249 text figures including 32 sphygmograms 92 polygraphic tracings, and 87 electro-cardiograms

NEW SECOND EDITION, 21s net

By great care and by the use of an amazing amount of material, he has accomplished what many readers have been waiting for, giving us a complete account of the diagnosis prognosis and treatment of heart diseases by modern methods in association with all the invaluable teaching bequeathed to us by the older masters of clinical observations —LANCET

The most valuable and comprehensive guide to the study of Cardiology with which we are acquainted —NEW YORK MEDICAL JOURNAL AND RECORD

We think that most of our readers engaged in general practice will find this work extremely useful —THE JOURNAL OF CLINICAL RESEARCH

In our opinion the book is indisputably the most authoritative contribution to cardiology of our time —FRANCO BRITISH MEDICAL REVIEW

A book which we believe is destined to remain the standard work on Cardiology for many years to come —AMERICAN MEDICINE

The second edition of this popular work on heart diseases bears evidence of thorough revision while the essentially clinical standpoint of the writer is maintained —EDINBURGH MEDICAL JOURNAL

It may be said at once that the book adequately fulfils the purpose it has in view and is a perfectly sound, lucid and reliable guide —NEWCASTLE MEDICAL JOURNAL

Well written concise, and complete containing a wealth of practical information Obviously based upon the author's own experience and investigative work —SURGERY GYNECOLOGY AND OBSTETRICS (Official Journal of the American College of Surgeons)

Dr Price is to be congratulated again on the reappearance in its second edition of his distinguished contribution to the increasingly important subject of Cardiology —THE CANADIAN JOURNAL OF MEDICINE AND SURGERY

OXFORD UNIVERSITY PRESS, Amen House, Warwick Square, London, E C 4

THE CLINICAL JOURNAL.

6d. An Illustrated Weekly Record of CLINICAL MEDICINE and SURGERY **6d.**

Including a Section on MEDICAL PROGRESS dealing concisely with the most important advances

" my weekly perusal of the 'Clinical Journal' was a very important factor in my medical education "

***Special Leaflet with selected list of articles and other details on application —SIR THOMAS HORDER.

"The Rose Corset-Belt"

for Accurate Abdominal Support and Comfort

Extract from the "British Medical Journal,' Dec. 10th, 1927—

Visceroptosis is the cause of so much discomfort and ill health and an ill fitting or wrongly applied belt or corset may aggravate rather than diminish the subjective effects of this condition Madame Rose has for many years devoted special attention to this problem and we have good reason to believe that she has given help and comfort to a considerable number of sufferers We have received assurances from medical men who have sent patients to her that she gives personal attention to each patient that she takes great care in adapting and adjusting the support to the particular needs of the case

WHEN YOU PRESCRIBE WARMTH WITH FRESH AIR

All medical men will agree that the practice of heaping thick, stuffy fabrics on the body to keep out the cold is merely increasing the risk of winter chills and influenza. The skin needs ventilation—the impurities in the air round the body must be allowed to escape. Fresh air must have access. Perspiration must be absorbed. That is why Jaeger underwear, made of pure Jaeger wool, is so often recommended as the healthiest underwear for all seasons All Jaeger underwear is treated against shrinkage. And there are Jaeger Agents in every town.

YOU RECOMMEND JAEGER PURE WOOL UNDERWEAR!

DEAF DOCTORS
AND DEAF PATIENTS

have proved "ARDENTE" a boon—a Heart Specialist whose work is so dependent on his hearing writes *"'Ardente' is a godsend to me"*, without "ARDENTE" he is, to all intents and purposes, "stone" deaf, with "ARDENTE" he carries on his work—what better testimony to "ARDENTE" merit?

Mr Dent makes a Stethoscope specially for deaf Doctors—the only one of its kind which is widely used and praised. Doctors whose work lies amongst the deaf prefer to prescribe ARDENTE because they know that ARDENTE is the only individual method in the whole deaf world (no mass production way can ever succeed with human disabilities) and they know what "ARDENTE" service stands for to the deaf. Many doctors who are deaf use ARDENTE

ARDENTE is entirely different and unequalled and succeeds in widely differing cases. A full range covers the needs of those suffering from varying forms and degrees of deafness and tinnitus. Minutely adjusted to the requirements of the case for young middle-aged or old and so sensitive as to have the desired effect even in middle ear and nerve cases bringing into action and stimulating the auditory system enabling it to function naturally and saving atrophy. ARDENTE can be used or not as it will, and is sold under guarantee.

ARDENTE is the choice of Doctor and patient—*only after test* and hearing or from prescription or particulars is ARDENTE fitted, toned, tried, adjusted, supplied and serviced.

Tests and demonstrations given at Doctors', patients' or our addresses, without fee or obligation

A Valuable Safeguard

against

Respiratory Tract Infections

It has been established as a result of biological experiments that a deficiency of Vitamin A tends to predispose to changes in the epithelial lining of the mucous tract, thus allowing for the occurrence of infection *(Brit Jour Exp Path* 1924 v 300) and, further that there has been found a *transformation of various epithelia into a stratified squamous keratinising epithelium* this change being *practically constant in the upper respiratory tract including the whole of the nasal passages larynx, trachea and bronchi (Lancet* April 28th, 1928, 881)

The regular ingestion of Radio-Malt ensures the necessary amount of Vitamin A to overcome these conditions and thus to safeguard against attacks of common cold, bronchitis and other diseases of the respiratory tract whilst there are still further advantages accruing from its standardised content of Vitamins B_1 B_2 and D

RADIO-MALT

INFLUENZA

The experience of Physicians who have used Mulford Influenza Serobacterin Mixed in industrial institutions and private practice, has confirmed their belief in its efficiency, both as a prophylactic and therapeutic agent

The structural formula of Mulford Influenza Serobacterin Mixed has been maintained unchanged since its introduction in 1910 but in the meantime particularly during the influenza epidemic of 1918 new strains of bacteria have been added, thus increasing its polyvalency and efficiency These bacteria include

Influenza Bacillus (Pfeiffer)
Streptococcus (hemolytic and viridans)
Staphylococcus (aureus and albus)
Pneumococcus (Types I II III IV)
Micrococcus catarrhalis
Bacillus Friedlander

As immunity is only relative there is an advantage in four injections, beginning with a small initial dose, progressively increased, thus affording a more complete and lasting immunity

Influenza Serobacterin Mixed is supplied as follows

M 109-0—	4 Vial Package	1 immunization
M 109 9—	5 " Vial	2 immunizations
M 109 4—	20 " Vial	8 immunizations

MALNUTRITION and MARASMUS

Mellin's Food has met with very remarkable success in the treatment of infants of retarded development due to nutritional disorders Infants in this condition need a food substance that is assimilated quickly and one that may be taken in comparatively large amounts

The carbohydrate maltose, which is the principal sugar in Mellin's Food, is a food substance that offers the greatest assistance in the adjustment of the diet because it yields immediately available nutrition and can be at once utilised to furnish the necessary heat and energy.

Mellin's Food

"MODIFIED MILK IN INFANT FEEDING"

The above-named booklet of 64 pages which gives further information regarding the use of Mellin's Food in cases of malnutrition, will be gladly sent to Members of the Medical Profession

Monsol Medicated Soap 8d

Monsol Throat Pastilles 1/3&2/3

THE mere statement that the R W coefficient of an antiseptic is 2, 20, or even 50, is of little value in estimating its usefulness for any variety of purposes The test organism employed in this method is B Typhosus, and an antiseptic which will kill this organism in high dilution will not necessarily kill others under similar conditions

The coal-tar group of antiseptics has a selective action on bacilli of the typhoid-coli group, with the consequence that Rideal-Walker coefficients for these products are remarkably and deceptively high If the same test is performed using a variety of other organisms, it will commonly be found that there are no two distinct varieties for which the coefficient is the same

The selective action of Monsol differs from that of any other antiseptic known Perhaps its most valuable action is on the Streptococcus Pyogenes, which Monsol destroys at dilutions 10 times greater than those at which phenol or Lysol are effective

Monsol is bland in action and in therapeutic concentrations non irritant even to mucous membranes

In Gonorrhoea

For irrigation treatment of gonorrhoea Acriflavine BD is the antiseptic of choice. While well tolerated by the tissues it is highly toxic to the gonococcus even at great dilution it inhibits the development of this organism

Acriflavine BD is issued in powder form also in tablets in solution, in an ointment, in bougies and in suppositories

To obtain the original British Acriflavine, BD Brand should be specified.

REGETHERM POULTICE

(Cataplasma Kaolini. B.P.C.)

CLEAN & CONVENIENT IN USE

More certain in its action than the old-fashioned poultice.

The healing action of Regetherm Antiphlogistic Poultice is governed by its ability to prolong and maintain an even degree of heat over a lengthy period. Moreover the ingredients are so balanced that this action does not set up any counter irritation but allays pain ensures an even circulation through the congested areas and thus induces natural and pain-free rest

The Medical Profession will appreciate the fact that the action of Regetherm Poultice is much superior to that of fomentations or linseed poultices and can be relied upon as an efficient aid in the treatment of all types of inflammation—whether local and superficial or of deep-seated origin

PRICE 2/- PER 1-lb. TIN

(NOTE THE WEIGHT)

Full size trial sample free to any medical practitioner in British Isles, on application by postcard to Boots the Chemists, Station St., Nottingham.

OVALTINE

WHEN SLEEP IS DIFFICULT

Judged by the numerous reports received from physicians and also from grateful patients, the use of "Ovaltine" for ensuring sound refreshing sleep deserves the widest recommendation

It has been remarked that a more helpful prescription could not be wished for because

1 Taken last thing at night before retiring it exercises a pronounced sedative effect and one that is natural in every sense

2 It has a pleasantly soothing action on the stomach and nervous system, and does not cause the slightest digestive unrest, or occasion constipation

3 It promotes a sufficiency of healthful sleep without resource to hypnotic drugs

"Ovaltine" is a delicious concentrated extraction of malt, milk, and eggs, in the form of golden granules, which dissolve instantly in milk

Local Anæsthesia in Surgical Practice

UNUNITED FRACTURE

Typical Case.

M C A. aged 27 years

Diagnosis Ununited fracture of the right radius and ulna at the midpoint.

Operation Intramedullary autotransplant.

Anaesthesia Brachial block, 10 c.c. of 2 per cent. Novocain Adrenaline solution local infiltration for removal of graft.

Operation The patient was given ¼ grain morphine and 1/100 scopolamine at 9 a.m At 10 a.m the operation was performed Brachial anaesthesia was established with the patient sitting in a chair 10 c.c. of 2 per cent. Novocain Adrenaline being used A large rhomboid infiltration was then made on the anterior surface of the leg The site of the fractures was then reached by two incision and the ends of the bones freshened. With a large drill the narrow cavity was reamed out and dowels were prepared from bone removed from the tibia. These dowels were fitted into place, the wound sutured and the patient made an uneventful recovery The anaesthesia for the removal of the transplant was obtained by a subdermal infiltration of the leg and in addition the needle was carried down to the periosteum making an infiltration along the line of the transplant to be removed

—EXTRACT from PRACTICAL LOCAL ANAESTHESIA (Farr)

(Full technique of this and one hundred other operations under Local Anaesthesia will be found in the above work published by Henry Kimpton, 263 High Holborn London W C 1)

THE SAFEST LOCAL ANAESTHETIC

Ample supplies of Novocain are available for the use of Surgeons at all the chief Hospitals Specify "Novocain" for your next operation

Milk Intolerance.

For many years Benger's Food, as is well known, has been used by practitioners throughout the world as a routine diet in all gastric cases, debility, and in cases of milk intolerance The reason for this may be briefly stated —

Benger's Food is a special wheaten flour preparation containing, in suitable amount, the two natural digestive principles — Amylopsin and Trypsin — in a latent state

It is devised and expressly intended to be used in conjunction with fresh cows' milk, or diluted milk, if desired.

The two enzymes are in such condition as to exert their digestive powers under the condition which obtains during the preparation for use

The Amylopsin acts on the carbohydrates (Starch) of the Food and gradually changes it into soluble sugars (Dextrins and Maltose mainly, with a little Dextrose) more or less according to the length of time allowed for digestion

The Trypsin acts on the gluten of the flour and on the proteins (Casein, etc) of the milk so that the curd which forms is softened, and as a result it separates in the stomach in fine readily-digestible flocculi instead of large, often indigestible curds The extent of digestion can be varied, *it is important to note that complete pre-digestion can never take place*

Benger's Food contains no preservatives It is palatable and is free from rough irritant particles

These considerations show that Benger's Food is not merely a mechanical milk modifier — it is a real modifier of a peculiar character.

THE "LANCET"
describes it as "Mr Benger's admirable preparation"

ON
SYMPTOMS AND PATHOGENESIS OF THE HAEMORRHAGIC DIATHESIS

BY

H. LETHEBY TIDY, M.D., F.R.C.P.,

PHYSICIAN ST. THOMAS'S HOSPITAL.

The term "haemorrhagic diathesis" is applied to a condition in which without visible extravasation of blood tends to take place into the skin and from the mucous membranes. The group in the past has been usually known by the name of "primary purpura," but numerous other terms have been employed. Purpura is the most striking feature of the group, since its occurrence as a primary symptom is confined to this entity, but it is not invariably necessarily present. The essential characteristic of the disease is the tendency to spontaneous *haemorrhages*, and the nature of these may be very varied. In secondary purpura the symptomatology may be identical, but some recognizable primary disease is present. Haemophilia, however, is a syndrome of a different nature.

PATHOGENESIS

The cause of these haemorrhages is still in doubt. Various organs and tissues have been held to be initially at fault, and the influence and action of these will be considered below.

Increased Capillary Permeability.—The small size of many of the cutaneous haemorrhages leaves no doubt that the blood has escaped from the capillaries. It is well known that the blood cells are able, in certain circumstances, to traverse the walls of these vessels. An increase in the permeability of the endothelium of the capillaries on reaching a certain stage would permit the blood cells to escape through the vessel walls in such a degree as to result in the appearance of cutaneous and other haemorrhages, depending on the site and extent of the change. Is there any evidence for the occurrence of such undue permeability in the haemorrhagic diathesis? As the permeability increases from its normal grade it will reach a point at which it permits the passage of an increased amount of plasma but not of cells. Accumulations of such plasma must manifest themselves as wheals, local oedema of the tissues, and urticaria. Lewis[1] in his study of the blood vessels of the skin came to the conclusion that skin stimulation produces wheals by causing active dilatation and increased permeability of the minute endothelial cells. The fluid present was proved to be blood plasma. Therefore if increased permeability is the cause of primary haemorrhages we would expect in the haemorrhagic diathesis to find the occurrence of local oedemas and urticaria. It is well recognized that this is so.

Clinically in certain types of the haemorrhagic diathesis there is close relationship between the occurrence of wheals and urticaria and the occurrence of purpura and ecchymoses. For example in a given individual attacks of urticaria and of haemorrhages may alternate, or both may be present simultaneously. This is referred to further under "Symptomatology." Obviously it may be accepted but in such cases the formation of wheals and of urticaria, and the occurrence of haemorrhages are due to the same factor. A striking phenomenon to which Lewis called attention is the occurrence of "refractoriness" in the minuter vessels. If a wheal is produced by skin stimulation the site affected will not produce another wheal until after the lapse of some days. For that period it is refractory to the same or similar stimuli. In refractoriness the minute vessels are dilated and do not respond either to vaso-constrictor substance or on the other hand to histamine or causes of increased permeability. Lewis decided that this is a direct property of the blood vessels. Apparently the same phenomenon occurs in the haemorrhagic diathesis. Osler[2] in 1811 recorded a case in which a mustard leaf was placed on the epigastrium of a man on account of a sudden pain. In fact this pain was the first symptom of the onset of acute purpura haemorrhagica, and on the next day the purpura appeared, and eventually haemorrhages extended over the entire body, except the site which had been covered and stimulated by the mustard leaf. In a case of mine, a man had a pain in the knee, which he thought was due to a strain, and for which he put on an elastic knee-cap. Purpura subsequently developed. When I saw him both lower extremities were covered with spots, except the area which had been compressed by the knee-cap, which was entirely free. It may be suggested that the refractoriness in these purpuric cases is similar to that observed by Lewis and exhibits the relationship *between haemorrhage and wheal formation*. Bedson,[3] in experimental purpura, watched the mesenteric vessel under a microscope, and observed the haemorrhages forming by an "exaggerated type of diapedesis"—that is to say, an increased permeability. He noted that the current of blood was not slowed, which agrees with Lewis's conclusion that there is active dilatation of the minute vessel during wheal formation. Thus there are several lines of evidence suggesting that primary haemorrhages on the one hand and urticaria and wheal formation on the other, are allied manifestations due to undue permeability of the capillary endothelium. It may be noted here that in urticaria there is as far as is known, no marked variation in the number of platelets nor does the spleen enlarge. Observation however, are scanty.

The Influence of the Blood Platelets.—In case of the haemorrhagic diathesis when haemorrhages are occurring and especially if they are severe, the blood platelets are usually reduced in number and may be entirely absent. This has given rise to the theory that the diminution of platelets is the essential cause especially in the grave form known as purpura haemorrhagica. Frank[4] believed that thrombopenia only occurred in purpura haemorrhagica, *and not in other types or lesser grades of primary* haemorrhage. He held the view that the thrombopenia was due to a primary defective action of the bone marrow, and was the direct cause of the haemorrhage. For this reason he introduced the term "essential thrombocytopenic purpura haemorrhagica." Frank now agrees that another factor besides thrombopenia is necessary and this he finds in "microtrauma" such as pressure of bed clothes. It is now recognized that the platelets may be greatly reduced or even entirely absent, and yet no haemorrhages take place; this may be so in known cases of the haemorrhagic diathesis and also in other conditions in which reduction of platelets develops. Further, in a case of the haemorrhagic diathesis the platelets may be normal in number, even at a time when haemorrhages are definitely occurring—that is to say, when the disease is active. This is often found in the type known as Henoch's purpura. Bedson[3] was able to prepare an anti-platelet serum, injection of which resulted in complete absence of platelets in the blood of an animal, yet no purpura or haemorrhages appeared. But if subsequently a second serum was injected designed to act on the endothelium of the vessels then haemorrhages developed. No ordinary serum had such a result. Thus the absence of platelets does not result, by itself, in the occurrence of haemorrhages.

It has been argued that the absence of haemorrhage in complete thrombopenia is due to the presence of protective substances set free by the destruction of platelets. This argument is contradicted by the fact that haemorrhages result in experimental thrombopenia if an anti-blood vessel serum is injected. On the other hand this *serum does* not produce haemorrhages in a normal animal—that is with normal platelets. The conclusion appears to be that platelets have a protective action against the occurrence of capillary haemorrhages, but their absence is not a direct cause of such bleeding. The primary cause of the haemorrhage must be another factor. When this factor is absent haemorrhages will not occur whether platelets are present or not. When this *factor* is present the function of the platelets is to act as a protection, and this may be achieved partly or completely. Increased permeability of the capillary endothelium will fulfil the factor. With regard to the mode of the protective action of the platelets, the platelets possess two

Delivered to the Sheffield Medico-Chirurgical Society.

principal functions which are related to each other[8,9]. First, they tend to adhere in numbers, or even in masses, to injured endothelium. This has been observed taking place in injuries of capillary endothelium. In larger vessels it is now known that the white thrombi, which often cover or start from a patch of atheroma or other pathological site, are composed of platelets. The composition of these white thrombi long puzzled our predecessors. Secondly, platelets or their products are concerned in promoting the coagulation of blood. How far the coagulation time varies with the number of platelets will be discussed later. Both these functions tend to protect a site of capillary endothelium which is either injured by trauma or weakened in other manners. But if the demand is excessive, and frequently repeated, platelets will be consumed and thrombopenia result. Such thrombopenia is a secondary occurrence, and is the result, and not the cause, of the haemorrhagic diathesis. But it establishes a vicious circle, owing to the protective powers of the platelets being diminished.

The Influence of the Spleen.—A difficult question is the reason why the spleen sometimes enlarges in the haemorrhagic diathesis, and the nature of its activity. Kaznelson[10] discovered that cases of the haemorrhagic diathesis with thrombocytopenia benefited from splenectomy. He argued that the spleen produces a toxin which acts on the marrow, resulting in thrombopenia, and that the haemorrhages are due to this thrombopenia. As stated above, thrombopenia by itself is insufficient to account for haemorrhage. Kaznelson's theory might be modified to suppose the existence of a splenic toxin acting on the capillary endothelium and causing increased permeability. Such a toxin might be a histamine-like body. On this theory the spleen is the primary cause of the haemorrhagic state. There is no doubt that splenectomy generally has this beneficial effect in the haemorrhagic diathesis. The strongest evidence for the existence of a primary splenic action on the vessels is the frequent occurrence of cases in which haemorrhages cease after splenectomy although thrombopenia persists. But, on the other hand, haemorrhages will sometimes recur, or continue, after operation. In explanation of these recurrences it has been suggested that the reticulo-endothelial tissues elsewhere take up the activities of the spleen and produce an identical toxin. It is difficult to prove or disprove such a suggestion. Since time must elapse before the reticulo-endothelial tissues could develop such functions fully, this theory would not explain the cases occasionally met with in which the haemorrhages continue unaffected by splenectomy. Another theory is that the activity of the spleen is originally secondary to the haemorrhagic state, but results in a vicious circle. From this point of view the action of the spleen in acholuric jaundice is worth consideration. It is generally accepted that the primary fault in acholuric jaundice is the production by the marrow of a proportion of red cells of excessive fragility. The spleen treats these as effete, destroys them in large numbers, and enlarges spodogenously. The symptoms of acholuric jaundice are mainly due to the anaemia and other results of the excessive activity of the spleen, and are relieved by splenectomy, although the fragility remains. The operation removes a link in a vicious circle which has come into being but does not deal with the essential factor. There is no evidence subsequently that this excessive activity is taken over to any appreciable degree by the reticulo-endothelial tissues elsewhere.

It is possible that the spleen holds a similar and secondary position in relation to the haemorrhagic diathesis. Its increased action is thus explained as being destruction of defective platelets produced under stress by the marrow, or the disposal of debris of capillary haemorrhages. Splenectomy will permit these platelets, which are somewhat defective but still valuable, to remain in the circulation. The spleen is not always enlarged. In severe acute cases the spleen is rarely more than just palpable and frequently is not enlarged at all. This is consistent with the mode of action suggested. But, on the other hand, in chronic cases the larger the spleen the less marked in general are the haemorrhages. As we follow the increasing grade of splenomegaly we come to cases with definitely enlarged spleen, severe anaemia, a tendency to ecchymoses, and occasionally a few purpuric spots, and finally to cases of "splenic anaemia," often with no haemorrhages at all. All these latter grades usually benefit from splenectomy, but it is difficult to account for them on either of the two theories mentioned. In favour of a primary splenic action on the permeability of the blood vessels is the frequent cessation of haemorrhages after splenectomy. Against this view is the recurrence or persistence of haemorrhage in certain cases, the absence of any relation between the size of the spleen and the severity of the haemorrhages, and the absence of any obvious connexion between the spleen and the allied phenomena of urticaria. Cases of "splenic anaemia" are difficult to fit into either view.

The Influence of the Bone-marrow.—In fatal cases of the haemorrhagic diathesis there are no constant changes in the bone-marrow, and this is confirmed in the few instances in which biopsy has been performed. The marrow may be hyperplastic, aplastic, or apparently normal. It is known from other conditions that neither hyperplasia nor aplasia of marrow, even when extreme, is necessarily associated with the occurrence of haemorrhage. In agreement with these varying states of the marrow, there is no characteristic blood picture, either in acute or in chronic forms. The red cells, of course, are usually diminished in number, but may be normal or even above normal. Any of these changes in the red cells may be combined with increase or decrease of the white cells, probably depending on whether the bone marrow is, on the one hand hyperplastic, or on the other hand, either aplastic or temporarily exhausted. Diminution of red or white cells of itself does not result in capillary haemorrhage; such haemorrhages do not occur in persons bleeding to death or in many forms of advanced anaemia. The influence of the marrow in the haemorrhagic diathesis is therefore not primary, but secondary. Owing to exhaustion temporary or permanent it becomes unable to respond to the increased demand for platelets. The exhaustion may also apply to blood cells, and the degree can be measured by the resulting leucopenia.

The general conclusion may be drawn that the essential cause of the haemorrhages is an increase in the permeability of the capillary endothelium. The platelets attempt to protect the weak spots, and are thus removed from the circulation. Increased demands for platelets consequently fall on the bone marrow which may or may not respond successfully. The normal action of the spleen in destroying defective constituents of the blood increases, and the spleen tends to enlarge spodogenously. So far the position is fairly clear, though, of course open to alternative views. The doubtful points are why the capillary permeability varies and whether there is a primary action of the spleen causing this permeability.

SYMPTOMS OF THE HAEMORRHAGIC DIATHESIS

The cardinal feature naturally is the tendency to the occurrence of haemorrhages. The most characteristic form of haemorrhage are purpura, ecchymoses, and bleeding from the mucous membranes. The haemorrhages may be of any of these types, separately or together, and of any grade of severity and chronicity. The occurrence of the haemorrhages may be intermittent or continuous. Cases are met with in which fresh purpuric spots have appeared daily for many years. On the other hand, there may be complete freedom from haemorrhages for long periods. It is by no means invariable for haemorrhages to occur into the skin or into the subcutaneous tissues. Certainly the occurrence of these capillary haemorrhages into the skin often determines the diagnosis. Unfortunately the past purpura has been considered the essential phenomenon, and cases with other features of the haemorrhagic diathesis but without purpura have consequently been regarded as curiosities. A single mucous membrane may be repeatedly involved, such as the nose, kidney or uterus, or even the stomach, subsequently haemorrhages may develop at other sites, or a family history may reveal the nature of the bleeding. Most of these variations have received independent and elaborate names, especially in the absence of purpura. It may be noted that haemorrha

to the joints or the pleural cavity is very rare, but meningeal haemorrhage is not so uncommon

Although haemorrhages are the outstanding manifestation of the haemorrhagic diathesis, there is another factor to be considered in the production of symptoms As mentioned under 'Pathogenesis," the capillary endothelium may permit the passage of increased amounts of blood plasma without permitting the passage of blood cells This increased passage of plasma is the cause of ordinary wheal formation In different grades of severity it produces urticaria, and occurring in other sites it results in localized oedema of the subcutaneous and other tissues Such oedematous areas are rarely absent in cases of the haemorrhagic diathesis of more than slight severity, and are usually recognized without any difficulty when looked for They are often tender, and are usually ascribed to "deep haemorrhages," but it will be found that such areas frequently subside rapidly and without any ecchymoses or bruising When the tissues of the face are affected the appearance may closely resemble acute nephritis It is consequently of importance to consider what symptoms may occur in urticaria (including angioneurotic oedema or giant urticaria) uncomplicated by any haemorrhage There are two special groups First, abdominal pain, often colicky in nature, is a frequent symptom, and may be accompanied by diarrhoea and occasionally by vomiting With the diarrhoea there may be bleeding from the intestinal mucous membrane Secondly, the joints are often painful and sometimes swollen, and these swellings may subside with great rapidity There can be no doubt that these symptoms are due to effusions into the deeper tissues It will be observed that identical symptoms are prominent in certain forms of the haemorrhagic diathesis, and are rarely absent to some degree in any acute case

The symptomatology of the haemorrhagic diathesis consequently falls into three groups (1) the occurrence of haemorrhages (2) anaemia due to loss of blood and the drain on the blood-forming tissues (3) the results of escape of plasma into the tissues—namely, oedematous areas, abdominal colic, and pain and swelling of the joints The swelling may be considerable, but does not lead to the after-effects seen in the haemorrhages of haemophilia Splenic enlargement is variable In severe acute cases the spleen is rarely palpable at the onset, though it may become so after a few days In more chronic cases it may be noted that in general the larger the spleen the less severe are the haemorrhages, though anaemia is usually marked Unlike Banti's disease, the haemorrhagic diathesis never terminates in cirrhosis of the liver and ascites Females are generally believed to be affected more frequently than males In a consecutive series of twenty cases seen in private practice nine were males and eleven females, which may be regarded as equal Most cases are sporadic, but there is abundant evidence from the literature that the condition may be hereditary or familial, or both, and that inheritance may be through either sex Of these twenty cases, one male had a sister affected and one female had a mother affected There was no familial history in any of the others

Classification

The haemorrhagic diathesis has in the past usually been classified into the following groups (1) purpura simplex, (2) purpura rheumatica or Schonlein's purpura, (3) Henoch's purpura and (4) purpura haemorrhagica

For a long time it was considered that these groups were only slightly connected with each other Even recently it has been strongly held that purpura haemorrhagica is an entirely separate entity on the erroneous view that in this group alone are the platelets diminished and that any benefit follows splenectomy But in general the more correct view has been gaining ground that these groups possess common factors and to some extent represent degrees of severity Considering Henoch's purpura, the attacks of abdominal pain are the outstanding complaint With these attacks there is frequently diarrhoea, often with passage of blood Joint pains and swelling may also occur Not uncommonly the onset of these symptoms precedes any superficial haemorrhage On examination of a case of Henoch's purpura areas of oedema are usually easily recognized and are often extensive It will also be found in many cases that the superficial haemorrhages are mainly ecchymoses and that true purpuric spots are scanty These ecchymoses tend to be on swollen oedematous areas, the sites often being more urticarial than haemorrhagic The area of an ecchymosis is thus consistent with a small amount of blood cells and a large amount of plasma, the swelling being out of proportion to the staining The appearance can be produced by the injection of 1 or 2 c.cm. of saline subcutaneously in a haemorrhagic subject, the haemorrhage in such circumstances being probably due to the distension injuring capillaries which are already of less than normal resistance, the escaping blood cells being diluted by the excess of fluid present

In accordance with these observations, the degree of anaemia in Henoch's purpura may be comparatively slight, and the platelets may be normal or increased, the spleen is rarely palpable, or not more than the tip can be felt Thus the subject of Henoch's purpura is more ill than the severity of the haemorrhages and the condition of the blood would suggest He may be said to be more sick than purpuric and the symptoms are those attributable to the urticarial factor—that is to say, to the escape of plasma rather than of blood cells In general the anaemia appears to vary with the amount of purpura The oedema of the face may be sufficiently severe to produce a facies suggestive of acute nephritis Cerebral oedema may cause convulsions, and this is probably the origin of the statement that these cases often die of uraemia As might be expected the margin between Henoch's purpura and a state with severe haemorrhage is comparatively small The condition of Henoch's purpura may 'change to purpura haemorrhagica" Indeed, cases have been described as commencing with urticaria, developing Henoch's purpura and terminating as purpura haemorrhagica Experimental anaphylaxis may exhibit the same sequence in severe cases haemorrhage may occur and thrombopenia develop Clinically Weil[19] has recorded a case of a boy in whom urticaria followed the eating of eggs, the areas would sometimes become ecchymotic or on other occasions purpuric spots would be present In Henoch's purpura, therefore, the severity of the symptoms and of the constitutional disturbances is due to urticaria rather than to haemorrhage Consequently the severity of symptoms cannot correctly be considered to place Henoch's purpura as a step between purpura simplex and purpura haemorrhagica in degrees of severity of haemorrhage Henoch's purpura belongs to a subgroup in which urticaria and haemorrhages are both prominent Purpura rheumatica is clearly of the same type as Henoch's purpura, but of less severity

Excluding these two groups from the old classification, there remain purpura simplex and purpura haemorrhagica These groups may be considered as the limits of mildness and severity, and the terms may be regarded as indicating these states The grading must not be pressed too far, for the importance of haemorrhage depends not only on the extent, but on the duration Thus individuals with only a few purpuric spots may exhibit any degree of anaemia Unfortunately, also, this nomenclature leaves no title for the common cases in which the severity of the haemorrhages lies between these extremes, since, for reasons given above, Henoch's purpura cannot be placed correctly in this position

The complete entity which we are considering thus has three principal groups

1. *Pure Primary Haemorrhagia*.—All grades from 'purpura simplex to purpura haemorrhagica Symptoms attributable to anaemia are most prominent

2. *Pure Primary Urticaria*.—Characteristic symptoms are abdominal colic and joint pains

3 *Combined Haemorrhagia and Urticaria*.—This includes the forms Henoch's purpura and purpura rheumatica The most prominent symptoms are due mainly to the urticarial factor but this factor does not cause any drain on the blood forming organs or the necessity for the removal of debris from the tissues and the spleen does not enlarge from its activity

Changes in the Blood

Coagulation Time.—The coagulation time in the haemorrhagic diathesis is of considerable interest It is unfortunate that most records of coagulation time in the literature are of little value for comparison owing to failure to recognize or to report certain factors which

influence both normal and abnormal coagulation First, the method employed is of importance Dale and Laidlaw's method is satisfactory for clinical purposes Secondly, the temperature is of obvious importance, though often not mentioned The temperatures most often employed are 36° to 38° C and 25° C The blood temperature should always be used for one set of observations, though in certain circumstances the blood clots so rapidly as to make the experimental error disproportionately large At 25° C the clotting in pathological conditions may be so long as to make observations on consecutive drops a practical difficulty Probably 28° or 30° C would be the best alternative temperature, though these have been little used, and there are few observations for comparison A third factor of very great importance is the normal rapid variation in the coagulation time in successive drops from a prick Though dimly recognized previously, this was first clearly stated by Christie[7] For the first, second, third and for the fourth and subsequent drops at 37° C, the following average times may be given 2 min 10 sec, 1 min 5 sec, 45 sec, 40 sec Christie found that the same curve was given in cases of purpura, though with some prolongation—namely, 2 min 35 sec, 1 min 30 sec, 1 min 10 sec, 1 min 5 sec Other observers confirm the result that the coagulation time in the haemorrhagic diathesis tends to lengthen about 50 per cent with a fall in platelets, but not more According to Howel Evans,[9] the coagulation time rose about this degree as the number of platelets fell to 100,000 per c mm, but no increase follows any further fall Roskam,[18] in experimental thrombopenia in dogs, obtained a closely similar increase In my experience, in cases of the haemorrhagic diathesis with normal numbers of platelets, the coagulation time has been, if anything, shorter than normal

The following cases illustrate this point

1 J M, male, aged 53 years Symptoms of Henoch's purpura for six months Red cells, 5 900 000, haemoglobin, 90 per cent, white cells, 4,200 platelets, 340,000 Bleeding time, 1 min 40 sec Coagulation time at 37° C first drop 90 sec, second drop, 50 sec, third drop, 35 sec, fourth drop, 30 sec

2 R W, female, aged 30 years Spontaneous bruises for ten years Family history of "bleeders" Red cells, 5,700,000, haemoglobin, 80 per cent, white cells, 6 200, platelets, 370,000 Bleeding time, 2 min 45 sec Coagulation time at 37° C first drop, 75 sec, second drop, 35 sec, third drop, 35 sec

3 A B H, male, aged 60 years Purpura and epistaxis for fifteen years Blood pressure, 160 mm systolic No splenomegaly Red cells, 7 100,000, haemoglobin, 105 per cent, white cells, 11,200, platelets, 285,000 Bleeding time, more than 20 min Coagulation time at 37° C less than 30 sec in first drop

It would appear that in the haemorrhagic diathesis the basal coagulation time is as short as, or shorter than, normal The time lengthens with the fall in platelets, just as it does with experimental thrombopenia in otherwise normal animals, but this increase does not exceed about 50 to 70 per cent It is probable that this increase, together with some experimental error, has accounted for cases of the haemorrhagic diathesis occasionally being confused with haemophilia The great lengthening characteristic of haemophilia never occurs in the haemorrhagic diathesis In haemophilia, further, the coagulation time does not diminish in successive drops from a prick, but tends to lengthen

Failure of Clot Retraction—If blood is collected in a small test tube from a case of the haemorrhagic diathesis, it is frequently found that the clot after forming, fails to retract and to express serum This failure appears to run parallel with the diminution in platelets It is difficult to say what effect this would have on haemorrhage occurring from a small vessel A similar failure of retractability is frequently observed in many conditions in which there is no tendency to haemorrhages, or, so far as is known, any reduction in platelets

Bleeding Time—*This test, was introduced by Duke*[4] in order to obtain some direct measure of the haemorrhagic tendency The blood from a sharp prick is soaked off with filter paper without pressure every quarter to half a minute, and the length of time until bleeding has entirely ceased is noted The normal bleeding time is one to two and a half minutes The method has a suggestion of vagueness and may be tedious, and this no doubt accounts for its unpopularity In fact, it is a valuable test of the haemorrhagic state at the moment of examination, it is easy to perform, and the variations are often sufficiently great to leave no question of experimental error The lobe of the ear is the best site, and it is essential that no pressure should be employed The bleeding time may be greatly increased, even to an hour or more, in haemophilia and in the haemorrhagic diathesis In haemophilia it runs parallel with, and is undoubtedly associated with, the difficulty in coagulation But in the haemorrhagic diathesis the coagulation time cannot be an important factor in the bleeding time Roskam[18] found that enormous differences in the bleeding time existed in various cases with the same coagulation time Roskam also observed that in experimental thrombopenia the bleeding time increased about three times as the platelets fell to zero, the coagulation time having lengthened about 50 per cent Such an increase of the bleeding time is comparatively small in relation to the long duration often recorded in the haemorrhagic diathesis In the haemorrhagic diathesis the bleeding time does not correspond either to the number of platelets or to the length of the coagulation time Thus the great increase in the bleeding time cannot be principally due to variation in the number of platelets or in the coagulation time, though these are contributory factors It is found, however, that the bleeding time varies closely with the actual occurrence of active haemorrhage When the haemorrhages cease in an active case, the bleeding time will be found to have fallen almost to normal When they recur, the bleeding time will have lengthened again The platelets during these changes may have remained constant This is well illustrated by the following case of Leschke and Wittkower[13]

Woman, aged 40 Purpura and Bleeding from Mucous Membranes for Eight Years

Date	Platelets	Bleeding Time	Haemorrhages
1924 March 29	10 000	60 min	Extensive
April 2	10 000	6 min	Bleedings ceased
„ 3	10 000	4 min	Skin clearing
„ 7	Splenectomy		
„ 25	13 000	2 hrs	Petechiae and mucous membranes bleeding again
„ 27	30 000	3 min	Bleedings ceased
„ 29	36 000	2 min 50 sec	Petechiae disappeared

Clearly the increase in the bleeding time depends essentially on the activity of the factor which results in the haemorrhage, and this is consistent with the view that the primary factor is the permeability of the capillaries

Capillary Resistance Test—This test is also known as Rumpel-Leede's or Hess's test A tourniquet is placed round the upper arm and the pressure raised as in estimating blood pressure In active states of the haemorrhagic diathesis, purpuric spots will appear on the lower arm The test needs standardization both for the height of the pressure and for its duration, as Lewis[14] has shown Probably two minutes is the best duration The pressure should be just sufficient to obliterate the pulse at the wrist With these standards the production of purpura is evidence of an active haemorrhagic state The results run parallel with the bleeding test The crop of spots is sometimes very extensive, and the patient may be alarmed at their appearance It must be noted that in a case of the haemorrhagic diathesis, an increased bleeding time and a positive capillary resistance test are evidence of *activity* at the moment, and also form a measure of the degree of the activity But their absence does not necessarily prove that the patient is not a subject of the diathesis

CHANGES IN THE BLOOD CELLS AND PLATELETS

As stated above, there is no characteristic blood count Since there is direct loss of blood, the blood-forming tissues must be called upon to supply more blood cells, and to an even greater extent more platelets in view of their action described above The leucocytes, for example, may be consequently produced in sufficient numbers as the marrow reacts, or in excessive numbers, as also occurs

after severe haemorrhage, or in defective number, as the bone-marrow fails temporarily or permanently. Such is the probable explanation of the changes observed. Certainly the leucocytes may be increased or decreased and the differential count may show wide variations. With extreme leucopenia, high percentages of lymphocytes may occur. With regard to the red cells and haemoglobin diminution naturally is usual, but erythrocytosis is not unknown.

Blood Platelets.—Great differences in the number of platelets are found in different cases and the number may also vary with great rapidity in a given instance. With severe acute haemorrhages justifying the term "purpura haemorrhagica" the platelets are very scanty or absent. In such conditions the platelets may increase very rapidly with the cessation of active bleeding and may reach normal in a few days. The active bleeding has been observed to cease before the increase of platelets commences, as in the following case recorded by Koerber:[3]

Woman aged 48. Severe Purpura and Haemorrhages for Three Days.

Date	R B C	Hb	W B C	Platelets	Haemorrhages
June 5	5	80	11 600	Nil	Extensive
„ 8	3·5	60	9 200	„	Extensive
„ 10	2·8	35	11,100	„	Less: no haematuria
„ 11	2·2	25	10 000	„	Almost ceased
„ 12	1·8	30	11,200	„	Completely ceased
„ 13	1·7	35	9,900	6,900	
„ 14	1·8	35	11 400	340 000	
„ 20	2	35	7,000	200 000	

Diminution of platelets may be present with haemorrhages of lesser severity. In chronic cases of moderate or even slight severity the number is often between 80 000 to 150,000 per c.mm., and variations do not occur very rapidly. In conditions of moderate severity of short duration the count may be within normal limits. In Henoch's purpura, even with considerable pain and constitutional disturbances, the number is frequently normal, or may show an increase. Havem[4] in an early article, noted that diminution might occur in secondary purpura, but the observation apparently was overlooked.

Relation of the Haemorrhagic Diathesis to Certain Clinical Conditions

It is impossible to decide exactly what clinical groups are manifestations of the haemorrhagic diathesis. The difficulty, as usual, is mainly on the borderline where this and other entities merge together. Certain conditions may be referred to:

1 *Haemophilia.*—The lengthened coagulation time and the normal number of platelets need no further reference. It is noteworthy that purpura does not occur in haemophilia. It is now widely accepted that women are never haemophilics. There can be no doubt that nearly all alleged female haemophilics of the past (and some of the sporadic males) were cases of the haemorrhagic diathesis. Nevertheless there is an impression among many females of haemophilic stock that they bleed more profusely and readily than ordinary individuals, though never to the degree of a male haemophilic. There are no modern studies of this possibility. The moderate lengthening of the coagulation time in the haemorrhagic diathesis may cause difficulties in diagnosis. Certainly there is no direct connexion between the two entities.

2 *Secondary or Symptomatic Purpura.*—The groups of "secondary purpura" recorded in textbooks need revision. Thus purpura is not a feature of chronic leukaemia, indeed, the occurrence of any haemorrhage, even a few purpuric spots, heralds the termination of life in leukaemia. It may be doubted whether purpura can ever be justly attributed to jaundice. I do not recollect ever having seen purpura in the jaundice of gall stones. Some at least of the 'cachectic" purpuras are mythical. I have known a man with the haemorrhagic diathesis finally die from carcinoma of the stomach, in spite of extreme wasting and an advanced chronic anaemia he had no purpura in the last six months of his life. There is no proof that purpura occurs in acute rheumatic fever personally, I have never seen an example. Scurvy, of course, produces haemorrhages, but this is a vitamin deficiency and not cachexia. Nor does scurvy produce purpura. The influence of vitamin deficiency in the production of haemorrhages needs further investigation.

3 *Banti's Disease and Splenic Anaemia.*—These terms are often used as synonyms and even as synonyms for the haemorrhagic diathesis. There is no doubt that several different entities are thus confused. Banti's disease is distinct from splenic anaemia and has no relation to the haemorrhagic diathesis, neither of these latter conditions ever terminates in hepatic cirrhosis and ascites. Since Banti's disease was first described several entities have been separated from it such as the Egyptian form due to schistosomiasis. Banti's disease affects children and young adolescents. It does not occur in true adult life. The subjects are anaemic and icteroid, with palpable but not greatly enlarged spleens, and later the characteristic hepatic cirrhosis develops. The duration covers a few years. There is no purpura or ecchymoses. The entity has been confused by the pathology ascribed to it by Banti, which needs reconsideration. Splenic anaemia usually occurs in adults, but may be found in childhood. The spleen is markedly enlarged, and commonly reaches to the umbilicus. Anaemia is severe. The facies is usually extremely pale, but without the muddy icteroid complexion of Banti's disease. The duration is often very long and may be twenty or thirty years, but cirrhosis of the liver and ascites never develop.

It is difficult to know where to draw the line between splenic anaemia and the haemorrhagic diathesis. Cases of splenic anaemia are common with markedly enlarged spleens, advanced anaemia, and no record of any haemorrhage. If this group be considered alone, there is no reason for including it in the haemorrhagic diathesis, and on any of the theories in dispute it is difficult to account for the combination of splenic enlargement and absence of haemorrhage. But on the other hand gross haemorrhage, especially haematemesis, is a recognized feature of many cases of splenic anaemia. Formerly the gross haematemesis was usually ascribed to the large spleen kinking the gastric vessels, but haematemesis may occur in undoubted cases of the haemorrhagic diathesis, even in the absence of splenic enlargement, and may be safely attributed to oozing into the stomach. Possibly in splenic anaemia both causes are acting. A definite sequence can be traced between splenic anaemia without haemorrhage and cases of the fully developed haemorrhagic diathesis. Thus in the first step there are cases with recurrent haematemesis, then cases with occasional haematuria or rectal haemorrhage in addition to haematemesis, and then a further group with a few purpuric spots. It is noticeable that the size of the spleen tends to diminish as we pass from "splenic anaemia" to the definite haemorrhagic diathesis. The question is still unsettled, but it may prove that some of the cases of typical splenic anaemia without obvious haemorrhage belong to the haemorrhagic diathesis. Others may be separate entities. Banti's disease may be regarded as distinct.

4 *Aplastic Anaemia.*—In this syndrome there is severe anaemia, leucopenia, thrombopenia, and aplasia of the bone-marrow. The condition may be either primary, without obvious cause, or secondary. A simple secondary group is that produced by the action of certain coal-tar products—for example, T.N.T. The spleen may be palpable, but is not greatly enlarged. Haemorrhages may or may not occur in this group. The development of haemorrhages is partly explained by the thrombopenia, but the nature of the additional factor necessary is doubtful. There may be no evidence of sepsis. It must be remembered that the aplastic state is not confined to the bone-marrow, and the blood vessels may share in the dyscrasia. In the haemorrhagic diathesis the marrow may become aplastic from exhaustion. But many cases of aplastic anaemia have no connexion with the haemorrhagic diathesis, and the haemorrhages are a secondary phenomenon, indeed, the patient may die of anaemia without their occurrence.

5 *Haemorrhages from a Single Site*.—An individual may have recurrent haemorrhages from the same site over a course of years. The occurrence of these in splenic anaemia has already been mentioned, but there is a group without splenic enlargement and with variable degrees of anaemia. The most common forms are epistaxis, haematuria, and metrorrhagia, but no mucous membrane is immune, and recurrent haemorrhages from the rectum and elsewhere may occur. These cases often cause much anxiety. At one time it was commonly believed that a surgical cause existed in every instance. It is now becoming recognized that these may be manifestations of the haemorrhagic diathesis. Kidd[9] was the first to observe purpura of the bladder in cases of haematuria of this origin. Probably these cases are rare, and every care must be taken to ensure that other organic causes are not overlooked. In several instances frequent severe haemorrhages have ceased after splenectomy.

TREATMENT

Splenectomy.—Many successful results have been recorded from splenectomy in cases of the haemorrhagic diathesis. It is consequently important to consider in what instances it is indicated or advisable. The results which follow splenectomy in other conditions have now been studied in many cases. It is found that there is a temporary rise in leucocytes and in the blood platelets. This occurs very rapidly, and suggests the flooding of the circulating blood from the reserves. The leucocytes are mainly polymorphonuclears, the rise being of the same type as occurs after severe haemorrhages. Howel Evans[10] has shown that a similar rise in platelets may follow other operations. This rise reaches its maximum about the twelfth day, that is to say at the time when it is known that post-operative thrombosis most commonly occurs. In these conditions the platelets have usually returned to normal about the twentieth day, although leucocytosis may persist much longer. In the haemorrhagic diathesis a similar rise in platelets is frequently observed to occur after splenectomy. Previous to operation the marrow will be producing platelets as rapidly as is possible for its state at the moment. In accordance with this the rise in platelets may reach a very high number. Rosenthal[1] found that in such cases there was a considerable incidence of fatal thrombosis. In other cases, however, the marrow is either unable to produce so great a number, or possibly the demands consume all which are produced, consequently the rise in platelets is small or transient and in such conditions the risk of thrombosis is slight. In the haemorrhagic diathesis, consequently, there are two risks to be taken into account in splenectomy. First, the general risk of the operation, secondly, the special risk of excessive thrombocytosis with resulting thrombosis.

Usually we have to consider:

1. Is the patient ill enough to justify the general risk, or alternatively, too ill for any reasonable chance of recovery?
2. Is there a special grave risk of thrombosis?

With regard to the first point, the mortality from splenectomy in the very acute severe cases is very high. But on the other hand these cases practically all die, and unless rapid improvement follows blood transfusion, splenectomy gives the best chance of life. There is a large group of cases showing a chronic moderate grade of the haemorrhagic diathesis. Over many years there may be a tendency to bruising, some purpura, and occasional haemorrhages from mucous membranes. Many of these cases show no evidence of progressing and the disability is not severe enough to justify an operation. The decision as to splenectomy in an individual case will largely rest on whether or not the degree of chronic anaemia is such as to prevent the following of a normal routine. From the point of view of the subsequent prognosis, the number of the leucocytes is also a useful guide. If leucopenia is definite and persistent this points to exhaustion of the marrow. Such exhaustion may be a permanent aplasia, but the improvement which may occur shows that it is sometimes transient. Severe chronic anaemia and leucopenia are both indications for the performance of splenectomy. Many cases of this chronic moderate group show a definite leucocytosis. It is evident that the marrow is not exhausted and is reacting, and in general it is safe to wait if the number of leucocytes is normal or above normal. With regard to the special risk of thrombosis this undoubtedly exists in those cases in which the number of platelets is within or above normal limits. Probably the bone marrow is producing an increased number, and after splenectomy the count may rise to very high figures, and thrombosis occur. In some instances the haemorrhages may form a prominent feature while the platelets are still normal, as often happens in Henoch's purpura. If, however, the haemorrhages are becoming dangerous, the platelets will usually fall, and splenectomy then becomes safer. In such cases the risk is greater if operation is done too early, and the decision as to when to operate is sometimes difficult. Experience shows that an excessive rise of platelets will not occur subsequently if the number is appreciably below normal at the time of operation. A considerable number of cases of the haemorrhagic diathesis will fall into this group. The haemorrhages may be moderate and chronic, or of a severer grade. Splenectomy will be specially indicated if anaemia is advancing and leucopenia is present in addition to the low platelet count. In this group the risk from operation is not high in the hands of experienced operators.

The haemorrhages have sometimes been observed to cease with great rapidity after operation. It is even claimed that oozing may be seen to cease directly the spleen has been removed, but this may be doubted. In many cases no haemorrhages are observed after the operation is completed. This rapid result is probably due to the flooding with platelets described above. It is not uncommon for a few haemorrhages to occur subsequently in the course of the next few weeks and then cease, occasionally they occur later over prolonged periods. In general, the operation in the conditions described is very successful. The platelets frequently fall to their previous level and may even be completely absent without obvious haemorrhages occurring.

Blood Transfusion.—This is a very important method of treatment. In cases of severe haemorrhages blood transfusion should always be performed. This may of itself check the haemorrhages, and may be followed by complete cessation at least temporarily. Blood transfusion should in all cases be performed before operation for splenectomy.

Haemostatics.—Many attempts have been made to check the haemorrhages with haemostatics. Injections of whole blood have been repeatedly successful in the haemorrhages of newly born infants, but do not appear to have the same effect in children and adults. Numerous patent haemostatic preparations are in existence. No definite results can be ascribed to these. Possibly the usual dosage is too small as the value of some preparations is supported by experiment.

Calcium Salts.—The only object of injecting calcium salts must be to increase the coagulability of the blood. Observations show that the coagulation time is little altered, and any lengthening is due to deficiency of platelets and not of calcium. As might be expected, there is no obvious benefit from the use of calcium.

Other Forms of Treatment.—Intravenous injections of adrenaline 1 in 1,000 have been known to check the haemorrhages in children. Injections of T.A.B. vaccine have also been used with a view to obtaining an anaphylactic effect. This is not an irrational procedure, and successful results have been reported in children. In adults, and in many children, no benefit has been observed.

SUMMARY

1. The haemorrhages in the haemorrhagic diathesis are primarily due to increased permeability of the capillary endothelium.
2. Blood platelets normally protect the capillary endothelium, and the diminution in number observed in the haemorrhagic diathesis is secondary to this action.
3. Escape of plasma from the vessels accounts for certain of the symptoms, especially abdominal colic.
4. Haemorrhages from a single site—for example, haematuria—may occur.
5. There is no constant characteristic change in the blood cells.

6 No sharp dividing line separates the haemorrhagic diathesis from splenic anaemia, but Banti's disease and haemophilia are separate entities

7 Splenectomy is indicated and successful in severe cases, but is contraindicated unless the platelets are diminished in numbers

NON-FILARIAL ELEPHANTIASIS

BY

D J HARRIES DSc MD FRCS,

ASSISTANT SURGEON CARDIFF ROYAL INFIRMARY

A case of non-filarial elephantiasis recently treated at the Cardiff Royal Infirmary illustrates the value of a modified Kondoleon operation The patient had suffered for twenty-three years from a complaint which she had come to regard as incurable, and which not only caused her considerable discomfort, but, as she put it, entirely did away with any chances she might otherwise have had of finding a husband

History

The patient A B was 40 years of age At the age of 12 she suffered from a curvature of the spine tuberculous in origin and a tuberculous abscess on a rib When aged 15 she was stung on the left thigh by a wasp this soon got well At 17 the left ankle began to swell but the swelling disappeared overnight It then reappeared and gradually increased and a doctor was consulted He recommended a tight bandage from the knee to the ankle in the patient's opinion this drove the swelling from the leg into the thigh

In 1913 at the age of 23 she was admitted into Guy's Hospital where lymphangioplasty was performed without result She was again admitted to Guy's in 1920 and was operated upon by Mr Davies Colley The hospital notes were copied by the patient when the nurses were not looking These notes are so concise that they are quoted in full

The swelling extends from the ankle to Poupart's ligament anteriorly and to the level of the iliac crest posteriorly Patient has angular curvature of the spine

X ray Report—Old caries of the fifth lumbar spine probably tuberculous hip joint negative

December 9th 1920—Operation by Mr Davies Colley Anaesthetic C and E followed by ether A U-shaped incision was made on the dorsum of the left thigh the loop of the U being about a handbreadth above the knee joint the two limbs were carried up to the level of the lesser trochanter The flap of skin with the adherent adipose tissue was reflected upwards and the deep fascia exposed An elliptoidal flap of deep fascia was removed exposing the muscles of the thigh and some fat deep to the fascia This fat was not as translucent as that under the skin The enlargement of the limb was thus found to be due to increase of adipose tissue between the skin and deep fascia Some of the adipose tissue adherent to the skin reflected was excised The skin flap was reduced in size and stitched back. The calf of the same leg was treated in the same way

December 10th 1920—Wounds dressed much serous discharge

December 12th 1920—Wounds healing

January 12th 1921—Wounds healed Circumference of thigh on admission 29 inches now 26 inches The leg is diminished in size There is loss of cutaneous sensibility in a patch of skin below both incisions but deep sensibility is not impaired

Figures 1 and 2 showing the condition of the leg in October 1920 indicate the enormous increase in the size of the limb Figure 3 shows the condition on September 1st, 1929

Operation

The patient was admitted into the Cardiff Royal Infirmary on September 11th 1929—ten days after the third photograph was taken—and was operated upon on September 14th One incision was made in the thigh extending from the inner end of Poupart's ligament to the adductor tubercle of the femur another was made in the leg from a point one inch below the knee to the level of the internal malleolus and just posterior to the inner border of the tibia The deep fascia was considerably thickened and strips one inch wide were removed the whole length of the incisions The incisions were sutured with S W gut and healed in ten days

The patient left hospital on October 21st the limb showing very little improvement In January 1930 the oedema had almost completely disappeared from the lower half of the limb but the thigh was still almost as oedematous as before the operation

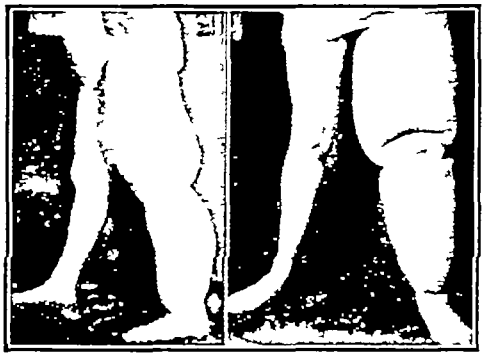

FIG. 1.

FIG. 2.

On May 7th I received a photograph (Fig 4) from the patient, with a note stating

> I think you will be interested to know that my leg has steadily improved since you saw it last January and I am enclosing photograph taken on May 5th 1930 I also desire to express my gratitude to you for such a successful operation It makes me very happy to be freed from an encumbrance which I have carried for so many years

The photographs speak for themselves The actual measurements at present are Right thigh, 20 inches left thigh, 21 inches, right calf, 12¾ inches, left calf, 13¼ inches

FIG 3.

FIG 4

COMMENTS

1 This case illustrates the value of Kondoleon's operation in elephantiasis

2 Hardly any improvement was seen during the first five weeks following the operation while the patient was still in hospital

3 The oedema gradually disappeared from below upwards, and the greater part of a year elapsed before the limb became normal

4 The incisions were planned to follow roughly the course of the main superficial lymphatic trunks It was considered that anastomoses between the superficial and deep lymphatics were more likely to form here than in any other area of the limb

5 The operation is easy to carry out, and appears to be devoid of risk

PLACENTAL HORMONES *

BY

J B COLLIP,

PROFESSOR OF BIOCHEMISTRY, MCGILL UNIVERSITY, MONTREAL

As a review of the literature and a progress report of our experiments on this subject has now been published elsewhere [2] a summary only of the work to date will now be given

The sulphosalicylic acid extract of human placenta made by the technique of Wiesner [3] has produced, when injected into immature female rats, increased rate of growth of ovary and the phenomena of oestrus Corpora lutea were present as a rule in the ovaries at the time oestrus was first observed The increased size of the ovaries was due for the most part to the newly formed luteal tissue This same extract, when injected into immature male rats, has produced an increased rate of growth of the prostate and seminal vesicles

Extracts of human placenta made by the use of acetone (equal volume) or alcohol (two volumes) were found to have similar physiological properties

Acetone or alcoholic extracts of human placenta which have been concentrated and fractionated with alcohol, have been divided into three parts, each of which appears to contain an active principle peculiar to itself and differing in certain properties from each of the other two The first fraction to be described contains the sex hormone oestrin, now to be known as theelin It is obtained by repeated extraction with ether of the acetic-acid acidified aqueous concentrate of the original extract, or of alcohol-soluble fractions obtained from the latter The second fraction represents the 85 per cent alcohol-soluble material present in the original extract, but from which oestrin has been removed by repeated extraction with ether Absolute removal of oestrin has been a matter of considerable difficulty and it has of late been our practice to extract ten times with ether, reacidifying the aqueous phase with acetic acid after each extraction The name emmenin has been suggested for the oestrogenic active principle of this fraction The third fraction consists of the material which has been precipitated from the original extracts by alcohol up to 85 per cent concentration This precipitate has been repeatedly extracted with water and reprecipitated by alcohol It has also been extracted with ether to remove oestrin For convenience this may be termed the anterior pituitary-like substance of the placenta The physiological properties of the second and third fractions only will be described

The second fraction referred to above has produced oestrus in immature rats in from three to seven days' time following either oral or subcutaneous administration In terms of the equivalent of original placenta tissue the smallest amount required to produce this result has been 0·5 gram per day Animals killed at the time of the induced premature oestrus have shown in gross and microscopic examination the typical oestrous changes in both uterus and vagina A slight increase in the size of the ovaries has been associated in many instances with increased development of the follicles Corpora lutea have not been observed in the ovaries at the time of the induced oestrus Similar results have been obtained with extracts of this fraction, which have been treated with pepsin or trypsin No demonstrable effects have ever been obtained in male rats either immature or adult by the injection or feeding of this fraction This fraction has been administered to normal adult female rats in doses varying from 1 to 10 grams of placenta daily or bi-daily over long periods The results of this study demonstrated conclusively that in the normal adult rat no interference with the oestrous cycle impregnation, pregnancy or lactation had occurred It has also been without effect on senile female rats A certain number of immature rats treated with the 85 per cent alcohol-soluble fraction appear to be immune to its effects and for this, as well as for other reasons, it is not possible at present to define the rat unit with any degree of certainty Another observation the significance of which is not clear, is that certain immature rats, which have been injected daily, although giving the usual oestrous response within a few days nevertheless have failed to show further oestrous cycles during the period of observation, which in some cases has been as long as nineteen days This is being further investigated The immature female rat may accept the male at the induced oestrous period, but in our experience implantation has not taken place until the second or third cycle Apparently corpora lutea must be present in the rat's ovaries if coitus is to be followed by pregnancy This is in agreement with observations of Crew [4] and others that puberty does not necessarily represent maturity

The physiological effects of the third fraction (85 per cent alcohol precipitate) have been studied along the same lines as the second fraction above described In *injection of this fraction into immature female rats has* been followed with remarkable uniformity, by the occurrence of oestrus usually on the fourth or fifth day Animals killed at this time have shown the usual phenomena of oestrus in both uterus and vagina but in addition the ovaries have been found to be considerably enlarged and to contain numerous corpora lutea in fact, the picture was practically identical with that obtained by the use of Wiesner's sulphosalicylic acid extract This alcohol-insoluble fraction was found to be ineffective when administered orally and it was destroyed by boiling Immature male rats injected with this fraction have manifested a definite increased rate of growth of the seminal vesicle and prostate gland in the course of ten days When the injections were continued for long periods the controls tended to equal the treated animals in regard to the *size of the accessory sexual apparatus* Adult males injected with this hormone also manifested hypertrophy of the accessory glands, but not of the gonads Adult female rats have continued to be cyclic with daily injections but manifested slight irregularities at times Normal pregnancy and lactation have also been observed during such continuous treatment Post-mortem findings have not as yet been of any significance

REMARKS

One must conclude from the results outlined above that the human placenta contains at least three distinct active principles or hormones These three substances are alike in that all have been observed to be oestrogenic in the immature female rat The active principle present in the second fraction (85 per cent alcohol-soluble) is very similar to oestrin in its ultimate physiological effects It is ineffective, however, in the castrate and hence it may be concluded that it functions directly or indirectly by stimulation of the intact ovary It also differs from oestrin in the degree to which it is effective by oral administration The third fraction prepared from the alcohol-insoluble material of the original extract is similar to the other two in that it is oestrogenic It differs from the emmenin fraction on three main points (1) it is ineffective by the oral route (2) it produces corpora lutea in the immature rat coincident with induced oestrus, (3) it causes an increase in the rate of growth of the accessory sex glands in the immature male

As yet we have been unable to obtain with surety from pig and cow placenta any of the above fractions other than oestrin This observation which must be given *further study* suggests that in the *human placenta* hormones exist which are absent in lower mammalian forms This suggestion receives support from the observation that pregnancy urine of certain of the lower forms has failed to give an Aschheim Zondek pregnancy test when injected into immature mice

The two oestrogenic placental hormones other than oestrin (theelin) which have been described appear to us to be the counterparts respectively in placenta of Prolan A (oestrogenic) and Prolan B (oestrogenic and luteinizing) of urine described by Zondek and Aschheim [1c7] We are also

* Read in opening a discussion in the Section of Obstetrics and Gynæcology at the Annual Meeting of the British Medical Association, July, 1930

of the opinion that these active principles are the specific products of placental tissue functioning and are actively related to the condition of pregnancy The functional interrelationship which must exist between the pituitary sex hormones and those of the placenta can in the light of our present knowledge only be conjectured Much more research must be done in this field before the data now available can be satisfactorily correlated

It is a great pleasure for me to state that through the kindness of the Medical Research Council and the National Institute for Medical Research I have recently been given facilities to repeat much of the work outlined above in Dr H H Dale s laboratory at Hampstead

NOTES ON THE CLINICAL USE OF CERTAIN PLACENTAL EXTRACTS

BY

A D CAMPBELL AND J B COLLIP

(From the Department of Obstetrics and Gynaecology and Biochemistry McGill University Montreal.)

THE process of menstruation in the normal state occurs every twenty-eight days from puberty to the menopause, except as interrupted by pregnancy and lactation Variations in the length of the interval the duration of the epoch, or in the amount of blood lost or endometrial tissue shed may not necessarily be considered pathological so long as such variations represent individual peculiarities The conception that physiological changes in the endometrium leading to menstruation are dependent upon chronological ovarian changes is now generally accepted Similarly, deviations from normal menstrual cycles, whether amenorrhoea, polymenorrhoea, or haemorrhage resulting from non malignant lesions of the endometrium, may likewise be considered as secondary to deranged ovarian function

Since Knauer[1] in 1896 first demonstrated the effect on the endometrium of ovarian transplants, scores of workers have used various products of glandular origin with a view to correcting menstrual disorders The demonstration that alcoholic extracts of the human placenta can be separated into three definite fractions, each having distinctive physiological properties, as described in the previous paper, suggests that a clinical trial of each of these fractions should be made The observations which are herein reported deal in the main with the possible therapeutic value of the 85 per cent alcohol soluble fraction (emmenin) A few clinical experiments with the so-called anterior pituitary like fraction of the placental extract (85 per cent alcohol precipitate) are also included As yet similar experiments involving the oestrin-containing fraction have not been carried out One hundred and twenty-three cases of deranged ovarian function as judged clinically have been treated and observed for periods

Read in the Section of Obstetrics and Gynaecology at the Annual Meeting of the British Medical Association Winnipeg 1930

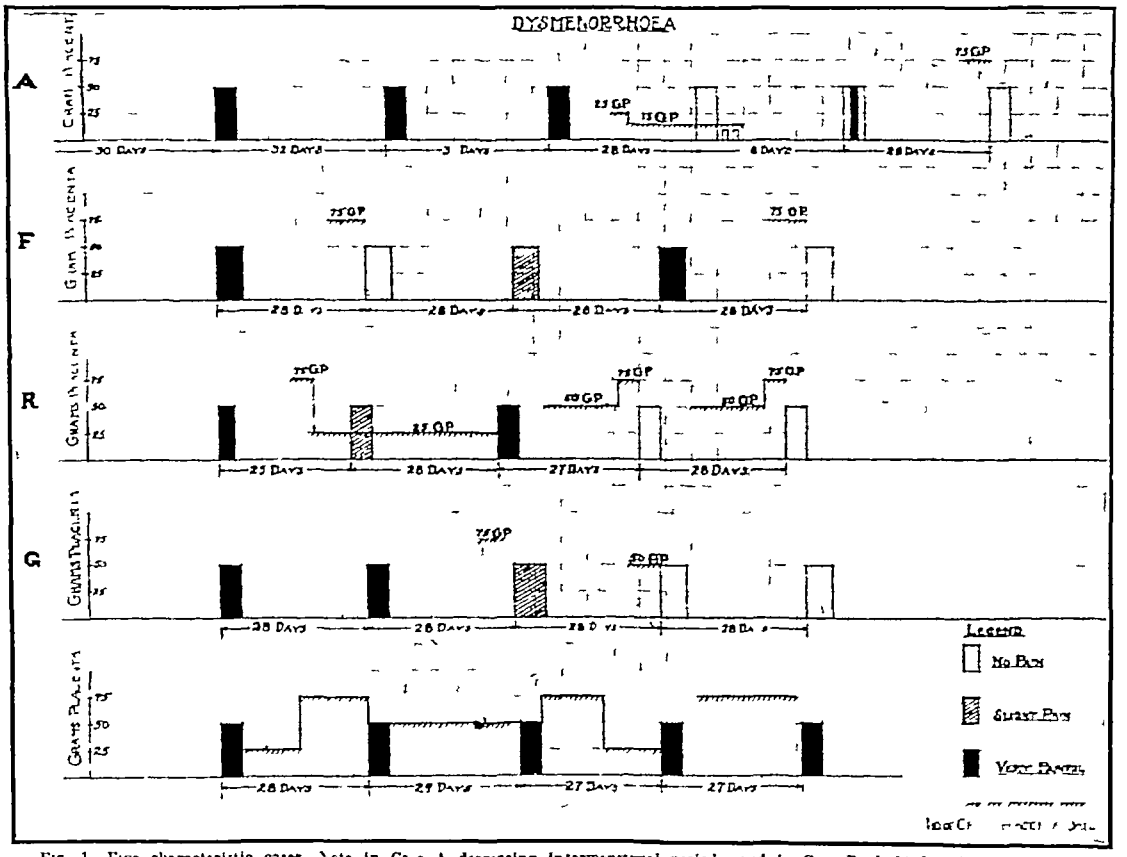

FIG 1.—Five characteristic cases Note in Case A decreasing intermenstrual periods, and in Case R slight lengthening of interval and period cycle being established in both cases at twenty-eight days. Case G stopped her extract two days before the period on one occasion and only had partial relief With proper administration complete relief was obtained. The fifth case was a problem even with varying dosage she received no benefit.

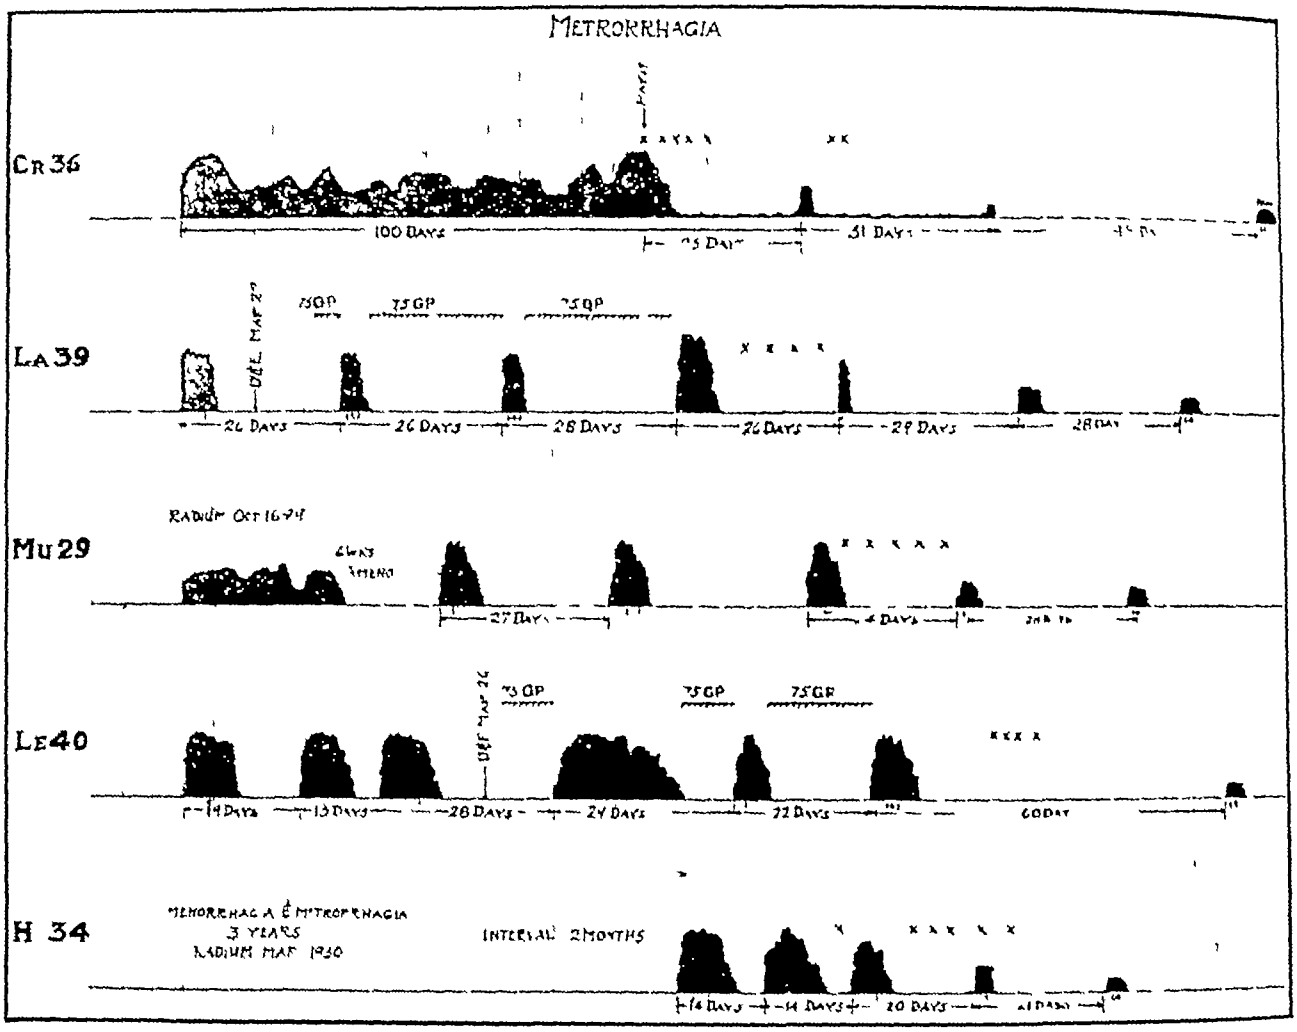

FIG. 2.—A purely diagrammatic chart to illustrate the non-effect of emmenin and the apparent effect of the anterior pituitary-like substance of the human placenta in the treatment of metrorrhagia. Injections of this latter extract are shown as X. 1½ to 2 c.cm. were administered, each cubic centimetre representing 25 grams of placenta, or approximately ten rat units. In both La 39 and Le 40 the condition was aggravated with emmenin but, as in the other cases, relief was obtained with the second principle.

varying from three to nine months. The general results are shown in the accompanying table. All the patients investigated were apparently normal individuals, and pelvic examination revealed no gross or obvious pathological conditions, either in the conformation and size of

Summary of Clinical Cases Treated with Emmenin

	Number of Cases	
	Treated	Improved
Amenorrhœa		
Primary	8	1
Secondary		
Oligomenorrhœa	20	13
Oligomenorrhœa (with lapses)	14	12
Regular (with lapse)	19	11
Polymenorrhœa	8	7
Dysmenorrhœa	35	25
Menopausal symptoms	18	14

the uterus or of its adnexa. From a study of such a comparatively small group of cases for a limited time, we are not justified in drawing final conclusions as to the possible therapeutic value of the agent employed. However, our impressions are as follows:

AMENORRHŒA

Primary Amenorrhœa.—The results in this group have not been encouraging. Out of eight cases in this group only one apparent success was obtained.

Secondary Amenorrhœa.—The cases of secondary amenorrhœa which have been studied have been arbitrarily placed in one of three groups, according to their histories:

1. *Oligomenorrhœa*: individuals with a diminished or scanty flow, and with periods occurring at irregular intervals of five to eight weeks.
2. Cases similar to No. 1 but having intervals of amenorrhœa of a duration of four months or more.
3. Those with normal menstrual cycles but with periods of amenorrhœa of upwards of four months' duration.

Encouraging results have been obtained in cases in each of these groups. The duration of the amenorrhœa proved to be of great importance, for no results were obtained where the condition had lasted for more than two and a half years.

We realize that, taken individually, any apparent success might be fortuitous. The apparent response to treatment of cases in this class occurred after an average period of twenty-three days.

POLYMENORRHŒA

Eight cases with intervals varying from eighteen to twenty-four days were treated. The intermenstrual period was increased in seven cases by four to eight days. A favourable effect on intermenstrual pain was also noted.

MENORRHAGIA AND METRORRHAGIA

No evidence was obtained which would indicate that the emmenin fraction of human placental extract is of any value in treatment of menorrhagia or metrorrhagia occurring either at puberty or in adult life.

DYSMENORRHŒA

It is possible that this condition is in some manner related to the lutein phase of ovarian activity. If the

uteral phase were absent during the earlier cycles of the human female (as it is known to be in a certain number of instances in the rat), a simple explanation might be had for the rarity of cases of dysmenorrhoea dating from the first menstrual cycle. Thirty-six cases of dysmenorrhoea have been studied and only two of these gave a history of the condition dating from the first cycle. Relief was obtained in twenty-six cases of this group.

MENOPAUSE

Observations of this type of case lead one to conclude that the duration of this symptom-complex is of prime importance, since no relief was obtained in cases of long standing whereas the symptoms were relieved for a time at least in certain cases where the condition was of recent origin—that is, less than one year since the last menstrual flow.

DOSAGE

A dose corresponding to 75 grams of placenta daily given in divided doses in water or orange juice before meals has been used in the majority of cases. There are individuals who do not tolerate the extract well. The cause of this we do not know, but in any case in which untoward symptoms, such as nausea or vertigo have been observed, the dose has been temporarily reduced until tolerance was acquired. According to our experience the use of emmenin does not seem to have any untoward effect on impregnation and gestation. It is worthy of note that four patients became pregnant while under treatment with emmenin for ovarian dysfunction. Thirty-six to forty-eight hours after the institution of therapy some patients volunteered that they experienced a feeling of general well-being and of mental alertness. No effect on libido was reported. As controls, ten cases with normal menstrual cycles were submitted to treatment for three months without any alteration being noted either in the length of the interval or in the duration of the epoch.

The dosage used in cases of dysmenorrhoea was, as a rule, the equivalent of 25 grams of placenta administered daily for approximately seventeen days, beginning with the cessation of a menstrual period. During the week preceding menstruation (twentieth to twenty-eighth day) the dose was raised to 75 grams daily, and treatment was continued until the onset of the flow, then stopped for a period of about a week. Other individuals with normal cycles obtained relief when treated for seven days preceding the anticipated period.

The second principle (85 per cent. alcohol precipitate of the anterior pituitary-like substance of placenta) was employed in metrorrhagia. The results in this small group of cases have been most encouraging (Fig. 2) and will be discussed in detail in a later communication. The extract used in these cases contained approximately ten rat units per cubic centimetre, and was administered subcutaneously. No enlargement of breasts or milk secretion occurred with the administration of this hormone. It should be noted here that the diagnosis is essential and that uterine exploration should *always* precede the treatment. Carcinoma as a cause of metrorrhagia, even in the young, must never be lost sight of.

Of 123 patients observed in this preliminary study basal metabolism determinations were carried out in practically all instances. 60 were detained in hospital for more detailed and special investigation according to the clinical indications. The sella turcica was x-rayed in 35 cases; sugar tolerance curves were taken in 27 instances, and blood cholesterol was estimated in 20 cases. The Wassermann reaction was carried out in all hospital cases, and this was negative in all cases treated. In three cases in which the basal rate was elevated, normal values followed treatment with emmenin. In another case, one of the oligomenorrhoea group, a mild diabetic condition was detected. No significant changes in blood chemistry have been noted as yet either before or after treatment, in any of the patients examined. Four cases which manifested the clinical signs of anterior lobe insufficiency were quite unaffected by treatment.

SUMMARY

1. Emmenin does not alter normal menstrual cycles.
2. Its effect in dysmenorrhoea has been particularly encouraging.
3. It appears to correct certain types of amenorrhoea of recent origin.
4. It definitely lengthens cycles in polymenorrhoea.
5. It relieves menopausal symptoms of recent origin, but does not relieve symptoms in castrates.
6. An anterior pituitary-like principle from the placenta arrests certain forms of metrorrhagia.
7. In the treatment of altered ovarian function the importance of a searching and accurate menstrual history, a detailed medical investigation, and in addition, a scrutinising pelvic examination, cannot be overestimated.

We wish to thank Drs. I. M. Rabinowitch and E. H. Mason for their kind co-operation in the study of cases which were treated in the Montreal General and Royal Victoria Hospitals. We are also especially indebted to Drs. Chipman, Fraser and Little for their advice and helpful criticism, and for the facilities which they have afforded to further this investigation.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL

DEVELOPMENTAL MIXED TUMOUR OF THE KIDNEY IN A PATIENT AGED 80

THE following case is an example of a rare tumour of the kidney occurring during the eightieth year.

History.—Mrs. S., while walking in the street after completing a morning's shopping, experienced a sudden and unbearable pain in the right side. When examined by Dr. Armstrong Atkinson shortly after the onset of the attack a large tender mass about seven inches in diameter could be felt in the position of the right kidney. There were no urinary symptoms and the urine was quite clear although it contained a trace of albumin.

Examination.—When I examined the patient she was in great agony but spoke of having been troubled many years previously by a movable kidney which he was always able to replace by manipulation. The mass in the right kidney area felt like a large acute hydronephrosis and the patient assured me that it had come with the attack of pain. The condition set up was so distressing that it was necessary at once to look and see what could be done to relieve the pain rather than to await the result of an *x* ray and ureter catheter examination.

Operation.—The same evening Dr. Armstrong Atkinson gave her an anaesthetic and I exposed the tumour by the oblique incision for the exposure of the kidney. The tumour was dark red in colour and was continuous at its upper and back part with the right kidney. The kidney therefore together with the growth was removed. There appeared to be no shock. The patient made a good recovery. After removal of the tumour and the kidney the tumour was found to spring from the pelvis of the kidney extending to the kidney substance. The microscopical report from the pathological department of the College of Medicine, Newcastle-upon-Tyne, was that the condition was a developmental mixed tumour of the kidney of varied structure and referred to as embryonal myosarcoma, non-striped muscle being a prominent feature in the case, conforming to the condition described by Wilms.

JOHN CLAY, F.R.C.S.
Surgical Director, Newcastle-upon-Tyne General Hospital.

OVARIAN CYST WITH TWISTED PEDICLE IN A CHILD

CASES of ovarian cyst with twisted pedicle are very uncommon in the literature. Kincaed and Andrews in the *American Journal of Obstetrics and Gynecology* (February, 1928), describe a case in a girl, 5 years old, differing only in that they report a palpable mass in the left lumbar region. The authors emphasize the difficulty of differentiating the condition from appendicitis. J. Morris (*British Medical Journal*, 1926, i, 944) records a case in a girl aged 4½ years, successfully treated by operation. J. Leveuf (*Semaine d. Hôp. de Paris*, June 30th, 1927)

reports a case of twisted ovarian cyst in a child of 21 months The majority of cysts of the ovary in childhood are dermoid cysts, these are four or five times as common as simple ovarian cysts with twisted pedicle

A consensus of opinion seems to point to the fact that ovarian cysts in childhood may be commoner than is supposed, but unless there is enlargement of the abdomen or a twisted pedicle the growth remains unnoticed, and these conditions rarely occur The following case occurred in the practice of Dr Robertson of Croydon

A girl now 4½ years old was reported to have had severe pain and persistent vomiting two years ago, the pain being referred to the hypogastric region She was treated medically, with intention to promote a free action of the bowels and improvement took place Two to three months later a similar attack followed and these attacks have recurred at about this interval since that time The bowels were regular with no tendency to constipation The temperature usually ranged from 99° to 100° F during the attack The pulse rate was 100 to 120 Flatulence was usually present The child had had bleeding from the vaginal passage when three days old it continued for one day No abnormal physical signs were reported

On December 6th, 1929, she had slight pains in the hypogastrium but felt better after the administration of syrup of figs had relieved the bowels Six days later the pain returned and was very severe, sleeplessness being complete There was no vomiting and no haemorrhage from the vagina or rectum The pain was of an intermittent character sometimes very severe, and never entirely absent The severity of the symptoms increased progressively and the bowels were constipated On December 14th the child was unable to sit down or stand up straight on account of the pain The urine was normal, and the temperature 99 6° F some definite but not marked rigidity was detected in the hypogastrium The child's general condition was good No mass could be felt, and laparotomy was advised for appendicitis

A left ovarian cyst with the Fallopian tube was removed on account of pedicle twisting The cyst occupied the left lumbar region in front of the left kidney it was 2¾ inches in diameter and free from adhesions or inflammatory exudate Recovery was uneventful, and was complete in ten days

The cyst was of a dark purple colour owing to extravasation of blood The appendix showed slight signs of congestion

I wish to thank Mr F M Cowell for permission to publish an account of this case

SEVERE FORMS OF RUBELLA

In view of the popular conception of rubella as a trivial indisposition, the following cases may be of interest

CASE I

A woman aged 40 developed swollen occipital glands nine days after exposure to infection Five days later a rash appeared on the chest and the temperature rose to 99° F The following day the rash was generalized typical, and very profuse The patient did not feel ill and refused to stay in bed but lay about in the garden the weather was very hot and dry On the third day after the appearance of the rash the knee joints became stiff, and the next day there was swelling of the knees wrists ankles and finger joints, with ulnar deviation of the hands and acute pain the feet also were painful The temperature was not raised but the axillary and crural glands were enlarged The patient was given 10 grains of aspirin three times a day as soon as the joint pain began by the seventh day after the appearance of the rash the swelling had disappeared and there was very little pain but some stiffness of the wrists, knees and shoulders By the end of the third week she was apparently quite well, although rather easily tired and the glands had not quite subsided She had had some fibrositis of her back and vague rheumatic pains at intervals for some years for which the tonsils had been removed but never articular rheumatism

CASE II

A girl aged 5 healthy though rather excitable developed a typical though scanty rubella rash with enlarged occipital and pre-auricular gland She was irritable, but not ill and the temperature was not raised Since she was an only child she was not kept in bed but did stay indoors On the fourth day of the illness she had rather an irritable food—namely pastry meat and carrots and about one pound of grapes eaten with their skins At 5.30 p.m. she suddenly said, "I can't see," rushed to the sink, and was violently sick, then collapsed on the floor At 6 p.m. she was comatose and flaccid, with the head and eyes deviated to the right, and saliva dribbling from the mouth At 7.30 she began to have right sided twitching, involving the face, arm, and leg She was given a rectal and stomach wash-out and 20 grains of chloral hydrate was left in the rectum The twitching continued until 9 p.m., after which she slept snoring and making sucking movements with her mouth At midnight she woke, and complained of a bad headache then slept naturally until 8 a.m. thereafter her convalescence was uneventful She had never had a convulsion before and has not had one since (two and a half years), in spite of having had whooping-cough and measles

CASE III

A woman, aged 34, with mitral stenosis following chorea and with a very large heart, complained of feeling ill for three days She always suffered from cough, and this was no worse than usual On the day she was seen she had begun to vomit She looked very ill, the temperature being 101° F, the pulse 120 and the respirations 32 She was sent home to bed On the following day she was still vomiting, and had several rigors A faint rash appeared on the chest, and the occipital axillary, and crural glands were enlarged and tender The rash became general on the face, body, and limbs, and was typical of rubella, she was seen by the medical officer of health, who agreed as to the diagnosis On the two days when the rash was at its height there was a temperature of 105° to 106° and signs of a lobar pneumonia of the left lower lobe The spleen was palpable On the seventh day there was a crisis, the temperature falling from 103° to 98°, and not rising again The rash and the lung signs gradually subsided a fine scaling taking place all over the body during the third week of the illness The patient regained her previous condition, and went away into the country whence she wrote to me later saying that she had had 'fluid on both knees," which had laid her up for three weeks

Sutton Surrey OLIVE POTTER, M B, B S

Reports of Societies.

TREATMENT OF FIBROSITIS

At the meeting of the Chelsea Clinical Society held on December 16th, with Dr F J McCANN in the chair, Sir THOMAS HORDER opened a discussion on the treatment of fibrositis

Sir Thomas Horder explained that he took the term "fibrositis" in the generic sense as including all the various inflammatory processes, rather than the older concept of muscular rheumatism It was not possible to consider the treatment of any disease without considering the etiological factors entering into it, and those which entered into the causation of fibrositis were very diverse They included, first of all, infection, then metabolic defects, and also defective nutrition in general, either under or over-nutrition Certain factors in the causation were outside control Fibrositic states were incidental to particular ages arthritis of the monarticular type was the heritage in the main of elderly people, for example, and at certain epochs of life—particularly on the female side but perhaps also on the male side—the individual was especially susceptible Other factors only partially if at all under control were occupation, climate, and the effect of trauma Microbic infection was thought to-day to be the dominant factor in most of the fibrositic diseases To such an extent had this idea come to prevail that in some textbooks on medicine the term "rheumatoid arthritis" had dropped out altogether It would be quite a good exercise to put the known clinical types of fibrositis in order according to the known dominance of the infective element The gouty patient, in Sir Thomas Horder's view, demonstrated two defects, one a tendency to metabolic dysfunction—purin dysfunction—and the other a microbic subinfection which in many instances activated the first There was something about the clinical picture of gout which was different from other exhibitions of focal sepsis, and it was not disposed of by changing one's view as to the mechanism by which the gouty state developed In rheumatoid arthritis there were etiological factors about

which at present there was complete ignorance It might be said as was said of gout, that there was probably in the majority of cases an infective factor, but it was not the only factor for a nutritional factor came into a number of cases, and a lowered nerve tone might exert some influence The effect of nerve control over infection or immunity had not yet been fully considered No doubt some cases of fibrositis owed their origin in the main to dental sepsis and it was right to examine the teeth very carefully, both radiologically and clinically, for devitalized teeth, gum recession deep pockets and the throwing out of the alveolar margin Guided by x rays and by his clinical experience of teeth and alveoli he sacrificed obviously infected teeth all devitalized teeth and all teeth concerning which the radiograms showed a definite early abscess formation at the root but as regards cases where the periodontal membrane was thickened or inflamed and there was a certain amount of recession of gum but the teeth were alive and useful mechanically, he required the patient to accept a certain amount of responsibility because there was a good deal of speculation about the advantage of sacrificing teeth of that description The ultimate decision on what was and what was not a septic tonsil had to be arrived at on much the same lines As to the prostate he had on two or three occasions been right in suspecting a prostate, concerning which there was a history," of being responsible for the state of fibrositis The state of the appendix and gall bladder was a matter calling for the exercise of clinical acumen If there were clinical reasons possibly also supported by radiology for suspecting the appendix and the gall bladder he would give the benefit of the doubt a little more readily to a fibrositic patient than to a patient who had no such disability He also drew attention to the possibility that in addition to the cul-de-sac to which he had drawn attention, there might be whole tracks of infection elsewhere—for example the nasopharynx and the intestinal mucosa So far as bactericidal erums were concerned, there was very little indication for their use in fibrositis apart from obvious acute microbic infection In the matter of vaccines the present position seemed to be one of indifference on the part of some practitioners disappointment on the part of more and tremendous keenness on the part of yet others Progenic cocci lent themselves very well to the production of antigen He thought that vaccination had not received as good a trial as it should have had in chronic intractable cases of fibrositis With regard to physiotherapy—and here he thought the best counterblast to the quack in this field would be a reputable Society of Physiotherapy—this in his opinion came next in importance to the method of dealing directly with the infection The question of the value, empirical or otherwise of some of the newer drugs and also of protein therapy he left to those who participated in the discussion

Dr C E SUNDELL said that one striking difference between the fibrous and other tissues was the relative avascularity of the former It was possible that some circulatory failure or anomaly might be at the basis of the fibrositic conditions In the parts affected capillary stasis was noted When dealing with the question of fibrositis it was a mistake to think merely of the late stage of the fibrous nodule the desirable thing was to spot" the patient who was likely to get the condition and prevent its further development He was quite certain that the question of heredity was of extreme importance Fibrositis was a later manifestation of an underlying state which might have been in existence from early childhood On taking the temperature of the fibrositic patient it would be found to be always subnormal and the basal metabolic rate was low His contention was that the treatment of fibrositis was in the hands of the physiotherapists By all means let them be guided by experts in searching the cul-de-sac but the treatment was to stimulate the circulation in the fibrositic areas and produce a proper action of the skin One must not allow oneself to be over-impressed by the exaggerated claims of the vaccinists The method of attack was first to discover the patient who was likely to get the condition, to stimulate his response to temperature changes, and do everything in one's power to make him a more healthy subject If the condition had already developed it should be dealt with on physiotherapeutic lines

Dr K I FECKENSTEIN said that in considering this subject it was necessary to put out of the mind all those conditions which could be called pathologically exact, and to deal with the vague cases which were the bugbear—though occasionally the triumph—of all physicians in which the patient complained of vague pains that were never very definite but were very difficult to cure Fibrositis was a typical example of one of these conditions, and it illustrated the truth in this particular respect of the remark that there is no such thing as disease, there are only diseased people"

Mr P JENNER VERRALL said that fibrositis came to the surgeon rather late With regard to the infective side, certain definite types of fibrositis were associated with some septic focus generally apical abscess Among these were tennis elbow" and painful heel" The former must not be regarded as peculiar to the players of tennis he had seen characteristic examples of it in those who scrubbed floors and performed similar operations He heartily agreed that the irritant was not necessarily a micro-organism it might be a chemical agent The whole question of fibrositis was not quite such a vague one as some speakers had suggested It boiled down to the orthopaedic principle of the circulating toxin be it chemical or microbic together with some local trauma not necessarily injury but perhaps constant pressure on a particular cartilage When the physician and the bacteriologist had cleared away the stasis physiotherapy was the treatment to follow An acute case was not suitable for any kind of osteopathy, it needed sedative massage, but there came a time in the development of the chronic case when the patient might well be put under an anaesthetic and bone setting manipulation be boldly done

Dr F TEMPLE GREY considered that the etiology of this condition must be viewed in a very broad way He thought that differences of temperament between different individuals had not been sufficiently considered in assessing susceptibility to infection Why did one kind of person escape or be seldom affected while another kind of person was particularly prone Dr J P FURBER mentioned that there was at present a vogue for deep x-ray therapy in the treatment of this condition, he could not say with what result

Dr J J MCCANN suggested that a large part of the profession had gone " eptic mad' He had been and would continue to be one of those who protected the teeth from wholesale extraction Pyorrhoea was not a disease of the teeth at all it was a disease of the gums, and was found in a well marked form when the teeth were in splendid condition He thought there was some danger in continually looking for septic foci because it might mean that the whole chemistry of the body was neglected Surely fibrositis a thing so widespread and affecting so many different people must have a common origin it could not be a septic focus A better explanation lay in the name which someone had given to it— tissue indigestion" A Frenchman had described it to him as due to congestion of the blood vessels and lymphatics, that was how it began It seemed to him largely a metabolic trouble

Sir THOMAS HORDER in a brief reply said that some of the things which had been discussed as causes seemed to him much more like effects for example, what was the cause of the capillary stasis—and was not subnormal temperature one of the expressions of the inflammatory state? He did not feel at all happy in the theory that these were the causes of fibrositis He was ready to admit that the influence of a micro-organism had been overestimated He had a feeling that the treatment on non-specific lines in cases of chronic fibrositis—the rheumatoid case—did good but he did not feel that it disposed of the infective factor to say that one would do better for the patient on non specific lines than on specific ones There was a danger with all infective processes of being content with the raising of a lowered resistance, and of leaving the microbic element alone

Reviews.

ENZYMES

In the latest addition to the Monographs on Biochemistry, Mr J B S HALDANE deals with *Enzymes*,[1] a subject of the greatest interest to most workers in biology and chemistry. Those who are not directly concerned with enzymes will find here a fund of ideas on other subjects. It is of interest to compare this book with that of the late Sir William Bayliss in the same series, published in 1908, in order to appreciate the great strides that have been made, not only in our knowledge of enzymes, but also in the physical chemistry involved. Perhaps the most striking change is in the attribution of definite shapes and sizes to molecules, which, for example, enables Mr Haldane to estimate the possible number of substrate molecules that may be packed on the surface of an enzyme particle, and suggest a diagram of their arrangement, while throughout the new book runs the idea of the variation in the degree of ionization of a weak electrolyte with hydrogen-ion concentration—an idea which does not appear in the older book.

Mr Haldane defines enzymes as soluble, colloidal, organic catalysts, thus narrowing the field by excluding crystalloid catalysts, such as glutathione, and surfaces of cells which lose their activity when broken up. This restriction, though artificial, is necessary in order to keep the size of the book within bounds. The catalytic nature of enzymes he regards as universally accepted, and he disposes shortly of supposed exceptions. The study of enzymes is therefore not concerned with the final state of equilibrium reached, but with the velocity of reaction, and throughout the book it is this kinetic aspect which is considered. In the chapter on the effect of hydrogen-ion concentration the theories of Michaelis—that only uncharged enzyme molecules are active—and of Northrop—that charged enzyme molecules act on substrate molecules of opposite charge—are discussed. It appears that some enzymes work in the first way and some in the second. Michaelis's theory of the effect of varying substrate concentration is considered, and important conclusions are drawn about the combination of enzymes with substrates and with inhibiting substances. Further chapters deal with the course of enzyme reactions, specificity, coenzymes etc., the poisoning of enzymes, the purification and chemical nature of enzymes, and theories of their action. Throughout a great wealth of actual examples is brought forward to illustrate every point.

The chapter on the course of enzyme actions is largely mathematical, but it can be skipped without missing anything essential to the rest of the book. Michaelis's theory of the relation between substrate concentration and velocity, besides a few other points, requires a certain amount of mathematics, but not of an advanced order. The author is somewhat over-inclined to assume that points which are obvious to himself will be obvious to the reader, but this is due to the extremely close style of writing, by means of which a phenomenal amount of fact and theory is packed into a short book. The bibliography occupies thirty pages, and there is a good index.

VISCERAL PAIN

The literature of pain is assuming vast proportions, but, with the exception of a few diagnostic compendiums and rare classical works, such as Hilton's *Rest and Pain*, the greater part of it has remained scattered through the journals. Visceral pain in the past decade or two has attracted particular attention, and students of the subject will therefore welcome the contribution by Drs LUNEDEI and GIANNONI of the University of Florence on Visceral Pain: Its Genesis and Characters.[2] The authors have embodied in their volume a critical review of the literature in all languages, and have given the old and the newer theories full consideration. The additions to our knowledge of referred phenomena in visceral disease which have accrued since the introduction of experiments made possible by regional and surface anæsthesia are carefully reviewed. The work of Mackenzie and Head and the English school in general finds frequent recognition, but curiously enough, there is no reference to the earlier observations of Ross and Hilton. The arrangement and the diagrams are good.

As a work of reference alone the book deserves a place on the shelves of all medical libraries. But it is much more than a work of reference, for the authors bring their critical faculties to bear on the problems involved, and both of them have recently published clinical and experimental observations which qualify them to write with some authority. There is much information included which should be of value to the practising physician and surgeon, and the writers of physiological textbooks, whose section dealing with visceral pain generally leave much to be desired, should also peruse the book with profit. With a growing interest in the special problems of symptomatology, and renewed enthusiasm for genuine clinical research, an English translation would surely be appreciated in this country and the United States.

GENITO-URINARY DISEASE IN CHILDREN

Diseases of the Genito-Urinary System in Infancy and Childhood,[3] by Dr HENRY I. HELMHOLZ and Dr SAMUEL AMBERG, is one of a series of monographs written for the general practitioner requiring information on any particular branch of medicine. Dr Helmholz is well known in this country for his investigations on urinary infections, and Dr Amberg for his contributions to the literature of diseases of children. Both authors hold professorial chairs in the University of Minnesota, and thus have special experience of teaching. They are therefore particularly fitted for the task they have undertaken. The only doubt that obtrudes itself is whether the overburdened general practitioner can afford time to read a work that deals with a specialty in a particular class of patient. His library may contain works on diseases of children and also on urology, but such specialized reading as genito-urinary diseases in children seems rather for the expert than for the general practitioner. However, if we assume that a practitioner can give his attention to such a small portion of the ground he has to cover, there is no doubt that he will find in this volume all and more than he requires.

The book contains eleven chapters, the first three of which deal with the embryology, anatomy and physiology of the genito-urinary tract, and the remaining eight with the disorders that may affect it. At the end of each chapter is appended a bibliography which allows the reader to go still more fully into any subject that may interest him. In passing, it may be noted that the references are mainly taken from American and German literature, and that few British or French writers are mentioned. In order to make the work as practical as possible considerable space is given in the chapter dealing with nephrosis to the subject of diet, and sample tables of different diets are appended, with their values in calories. In discussing nephrosis—by this term is meant a lesion of the kidney that is degenerative rather than obviously inflammatory in nature—the authors confess that we have not yet the material for a satisfactory classification of this disease. The chapter on pyuria, as might have been expected from Helmholz's interest in this subject, is undoubtedly one of the best in the book.

Lytle, M.D., and a *Comparative and Cumulative Supplement*, comprising vol. xxi. of the series, may be purchased for 32s.

NEW DRUGS FOR OLD

MODERN Pharmacotherapy[1] by Professor I. LIPOWSKI, is the tenth volume of a series entitled "Medical Practice" which is intended to provide medical men with information on recent advances in medical science. Dr. Lipowski treats his subject by considering groups of drugs, such as anaesthetics, hypnotics, antipyretics, etc. In each case he discusses important new drugs, and considers their advantages and disadvantages as compared with established remedies. For example, avertin anaesthesia is discussed at some length but the author declines to give any decisive opinion regarding the future of this method. Among the hypnotics the alkaloid banesterin or harmin is described as being of special value in the treatment of disorders of the motor system and in particular in the treatment of Parkinson's disease following encephalitis lethargica. In the same section it is interesting to note that dihodide, dihaudide, and eucodal are all accused of having produced extensive habit formation. The author remarks that the great army of "eucodalists" are comforted by the idea that eucodal is not a morphine derivative because it is made from thebaine, but he states that this drug has all the dangers of morphine possibly in an increased measure. The volume concludes with a section on organotherapy in which non-specific protein therapy is discussed. This form of therapy evidently has been pushed to almost absurd extremes in Germany but the author believes that it has a certain limited value in the treatment of chronic infections.

One of the interesting points about this short volume is that it shows differences between Continental and British opinion about the value of drugs. For example, camphor is regarded as a more important stimulant of the central nervous system than either strychnine or caffeine. Among the diuretics the new mercury compounds novasurol and salvrgan are discussed and special mention is made of the value of the combination of a diuretic with a narcotic of the veronal series. The whole volume in about 170 pages gives a very interesting summary of German opinion regarding the established merits of the more important of the new remedies that pour out in an unceasing stream from the great chemical factories of Germany.

DISEASES TRANSMITTED BY ANIMALS

THE book entitled *Diseases Transmitted by Animals to Man*[2] is mainly concerned with the bacterial and virus infections which are liable to come under the notice of the student of comparative medicine. Although it bears the stamp of a somewhat ill-digested preparation of the subject and deals mainly with it from the American point of view, it contains a considerable amount of useful information. Much of this is already well known to the British physician, who is probably better acquainted with comparative medicine than his American colleague, but it is useful to have it within the covers of a single volume. Mr. HULL groups his material into five sections. The first deals with the diseases of domestic animals, but does not include protozoal infections at all, and only discusses a few of the more obvious helminths. The second part is devoted to rodent infections but omits melioidosis. The third section considers such human diseases as are spread by animals, and the fourth such passively carried conditions as botulism, tetanus, and the gas gangrene group. The last section reviews the part played by each animal in the spread of disease. The volume is illustrated by forty-three tables and twenty-nine maps and photographs—one of the maps shows Denmark as the southern part of Sweden, and many are unduly large. While this book has obvious uses, it is evident that there is still room for a comprehensive work of reference on this most important subject, and it is equally evident that such a book cannot be written by a single worker in the subject, but must be the result of well-planned collaboration.

NOTES ON BOOKS

WITH its sixth edition Dr. LANGDON BROWN's book *Physiological Principles in Treatment*[3] attains its majority, and becomes the product of a collaboration. Dr. HILTON's name appearing with that of the original author on the title-page. The general character of the work must by now be well known to many of our readers. It deals in the main with derangements of metabolism, digestion, and excretion, and includes sections on organotherapy, and on certain circulatory and respiratory disorders. The authors' method—following the plan of previous editions—is to describe briefly the functions of the organ or system in question, to deal with tests employed as aids to diagnosis, and then to consider treatment in the light of the physiological disturbances that have been discussed. The book is written in a clear and lively manner, is very pleasant and stimulating to read, and should continue to prove of great value to physicians and general practitioners.

Colonel BIRDWOOD's *Clinical Methods for Students in Tropical Medicine*[4] has now reached a fourth edition, and the new work of the past ten years has been incorporated, so that the book is thoroughly up to date. In particular the sections on malarial fever and mosquitos have been revised, while there is a new section by Dr. Newham on preservation of pathological material, poisonous snakes, larvae, and worms.

It is not considered necessary in this country that textbooks on dermatology and syphilis should be written for the special benefit of the nursing profession, but in sparsely populated districts such as still exist in the United States of America and in the remoter portions of the British Empire, where nurses are often thrown much more upon their own resources than they are in this closely settled island, a little book such as that by Dr. STOKES[5] may prove useful. It is sound, and besides assisting the nurses who read it to become more efficient in their ordinary duties will be found to supply them with material for instructing the lay inhabitant in proper principles both as regards the use of soap and water and as regards the proper method of imparting sexual instruction to the young. It is rarely written with plenty of pep.

Professor GELLHORN of St. Louis has written a small, well illustrated and useful book *Gynecology for Nurses*[6] which might be read with advantage by all nurses engaged in general and surgical work. The illustrations of a male and a female hermaphrodite from a photograph and from a woodcut seem, however, to fall rather outside the scope of the title, as do the concluding eleven pages on the history of gynaecology, but a nurse without an inquiring mind will never rise very high in her profession.

Applied Electrocardiography[7] by PARSONNET and HYMAN, is described as an introduction to electrocardiography for physicians and students. It is well illustrated and handsomely produced. It contains a short summary of the physiological principles underlying the methods and a description of the galvanometer and its use. An account of the various abnormalities of rhythm is followed by a useful schema for reading tracings.

Less than five years have passed since the eighth edition of Dr. T. L. STEDMAN's *Practical Medical Dictionary*[8] was noticed in these columns and now we have before us the eleventh. This well-arranged and well-produced work of reference with its convenient thumb-index has now been familiar to the English-speaking medical public for nearly two decades, and its popularity may be judged by the constant demand for fresh editions. Though it has grown in size to keep pace with the ever-expanding vocabulary of medicine and the allied sciences, Stedman remains a dictionary of moderate dimensions. The present edition, which shows evidence of careful revision throughout, contains 76 more pages than the eighth and seven more plates, the full-page illustrations at one time gathered together at the end of the volume are once again

[3] *Physiological Principles in Treatment*. By W. Langdon Brown, M.D. Cantab., F.R.C.P. With the collaboration of R. Hilton, M.B. Cantab., F.R.C.P. Sixth edition. London: Baillière Tindall and Cox. 1930. (5½ × 7½ in. pp. ix + 564. 8 figures. 10s. 6d. net.)

[4] *Clinical Methods for Students in Tropical Medicine*. By G. T. Birdwood, M.D., D.P.H., Lieut.-Colonel I.M.S. Fourth edition. Calcutta and Simla: Thacker Spink and Co.; London: W. Thacker and Co. 1930. (Fcap. 8vo. pp. xiv + 366. 29 figures. 4 plates. Rs. 8/8.)

[5] *Dermatology and Syphilology for Nurses, including Social Hygiene*. By John H. Stokes, M.D. London: W. B. Saunders Company. 1930. (5½ × 8 in. pp. 311. 69 figures. 12s. net.)

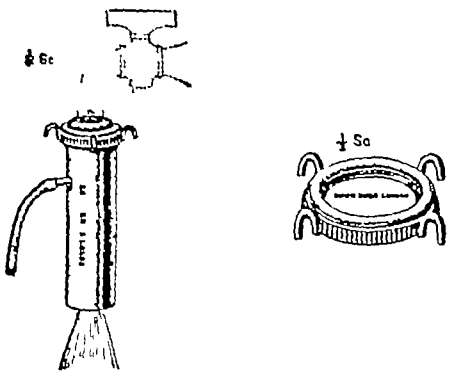
[6] *Gynecology for Nurses*. By George Gellhorn, M.D., F.A.C.S. Philadelphia and London: W. B. Saunders Company. 1930. (5½ × 8 in. pp. 275. 145 figures. 8s. 6d. net.)

[7] *Applied Electrocardiography*. By Aaron E. Parsonnet, M.D., F.A.C.P., and Albert S. Hyman, M.D., F.A.C.P. With a foreword by Harlow Brooks, M.D., F.A.C.P. New York: The Macmillan Company; London: Macmillan and Co., Ltd. (Pp. xxv + 206. 120 figures. 15s. net.)

[8] *Practical Medical Dictionary*. By Thomas Lathrop Stedman, A.M., M.D. Eleventh revised edition. London: Baillière, Tindall and Cox. 1930. (6½ × 9½ in. pp. xi + 1222. 440 figures. 22 plates. 35s. net.)

distributed through the text at appropriate places Definitions of words recently introduced into the physics of radiology are included in anticipation of their adoption into medicine and an especially thorough revision has been made of bacteriological terms in consequence of the recent changes in nomenclature proposed by the American Bacteriological Society In his preface, Dr Stedman expresses gratification at the success of his long continued efforts to purify medical spelling as shown by gradual adoption of his principles and practice by the two older medical dictionaries published in the United States But while he has saved the final e' of cesine and other alkaloids for American medicine and rightly prefers leucocyte to leukocyte, he rejects the "an English diphthong" in haemorrhage and oedema and in nearly all such words his dictionary departs from English usage

The new edition of *Whitaker's Almanack*[12] for 1931, which comprises about thirty more pages than the previous volume records with remarkable precision the changing conditions of modern life Aviation, for example has a dozen headings at least and the entries classified under 'women" have trebled in the course of the year While the new edition retains the familiar outlines of its predecessors there are noticeable improvements in several sections Legal notes are supplemented by a paragraph on vaccination and the scholastic section by a list of secondary schools for girls Public schools in the British Dominions are classified under a separate heading Two pages are devoted to porcelain marks—a feature we had not observed before In the political sphere the most obvious addition is a list of the names of members of the Senate and of the Chamber of Deputies of the Irish Free State Local government is discussed among questions of the day, which range from musical copyright to national mark beef Increasing attention appears to be given to social problems Statistics relating to crime are fuller than in the previous edition, and 'Crime and motors" is the title of an instructive article



Professor C G SELIGMAN has written a lucid introductory account of the *Races of Africa*,[13] describing their physical characteristics, social organization, and religious beliefs with some reference to medical practices It is regrettable that the need for compression demanded in the series to which the volume belongs has excluded pictorial representation, but there are one or two sketch maps illustrating the distribution of languages and geographical features

PREPARATIONS AND APPLIANCES

SUCTION PUMP FOR NOSE AND THROAT OPERATIONS

DR G A METCALFE (Bedford) writes For some time past I have been using a hydrostatic pump for obtaining suction in operations on the nose and throat, and have been greatly impressed by its value and efficiency One great drawback to the usual hydrostatic pump now in use is the fact that a good head of water, which is essential for its proper function,

tends to blow the pump off the tap I found great difficulty in securing it, and suggested to the makers that returning hooks should be fitted This has been done with the assistance of Messrs Down Bros, Ltd (St Thomas's Street S E 1) who have brazed to the lead four metal hooks, as illustrated, by which the pump can be easily and securely tied on It may be necessary to have a tap in the theatre adapted to the nozzle but this can be done by any plumber The rather objectionable noise of splashing can be silenced to a great extent by fixing a length of wide rubber tubing to the outlet and allowing it to open under water in a basin

A CHAMBER SEAT FOR INFANTILE RECTAL PROLAPSE

DR A H SHENAN (Johannesburg) writes Prolapse of the rectum in infants is a troublesome condition, its conservative treatment is tedious, always inconvenient, and often disappointing The prolapse may be present through various contributory causes, such as worms, polypus, constipation, and emaciation, but frequently no obvious reason can be discovered and in any case means must be employed to prevent the recurring descent of the mucous membrane or of the viscus itself during the prolonged treatment The accompanying sketch shows a special chamber seat which I designed and made for a patient of mine aged 15 months The points to be noted are (1) the thickness of the seat, with the edges

of the aperture bevelled to about 40 degrees, (2) the narrowness of the aperture laterally, and (3) the increased height from the ground In using the ordinary chamber the child sits low, the thighs flex sharply on the abdomen, and the buttocks sink through the rim, being pulled apart in the process With such a seat as the one here described the acute flexion is largely undone and the buttocks are forced together to give the required rectal support, the child's attendant, if necessary, tucking them in by hand

In the case of my patient the prolapse, which had previously taken place two or three times a day occurred thrice only during the following year No treatment was employed other than fattening the child, regulation of the bowels and use of the special seat After twelve months the device was discarded, and no further trouble was experienced

DENTIFRICES

The products sold in Great Britain under the familiar name of Odol have for some time past been manufactured in this country at Norwich Both the liquid dentifrice for use as a mouthwash, and the toothpaste sold in collapsible tubes, are very agreeable preparations, with antiseptic properties due to the presence of essential oils and of salicylic acid in combination

MEDICAL CONGRESSES, 1931

THE following congresses and conferences on medical and allied subjects have been announced for the ensuing year, 1931 Particulars are given below in the following order date name of organizing body place of meeting name of person to whom inquiries should be addressed More detailed information about these meetings is given from time to time as it becomes available, in the news columns of the *British Medical Journal*

April 9–10—German Psychiatric Society Breslau
April 12–16—Congress of Psychology Hamburg
April—German Balneological Society Bad Ems
May—Royal Institute of Public Health Frankfurt Secretary of Institute, 37, Russell Square W C 1
June 8–13—International Hospital Congress Vienna Professor Tandler, 9, Rathausstrasse, Vienna
June—International League against Trachoma Budapest
July 4–11—Royal Sanitary Institute Glasgow Secretary Institute, 90, Buckingham Palace Road, S W 1
July 21–25—British Medical Association Eastbourne Medical Secretary, British Medical Association, Tavistock Square, W C 1
July 27–31—International Congress of Radiology Paris Secretary of Congress, 34, Boulevard de Vaugirard Paris, XV
August 3–8—International Dental Congress Paris Mr A Rowlett, 165, London Road, Leicester
August—International Congress for Industrial Medicine Geneva Mr G L Peiry, Industrial Welfare Society, 51, Palace Street S W 1
August 31–September 4—International Congress of Neurology Bern
September 21—Faraday Centenary London Secretary Royal Institution, 21, Albemarle Street, W 1
September 23–30—British Association Centenary Meeting London Secretary of Association, Burlington House, Piccadilly W 1
October 14–18—International Congress of Comparative Pathology Paris Dr Grollet, 7, rue Gustave Nadaud, Paris 26
1931—International Congress against Alcoholism Warsaw
1931—International Congress of Military Medicine Budapest

MATERNITY WELFARE

MINISTRY OF HEALTH MEMORANDUM

It will be remembered that in July 1929, the Representative Body of the British Medical Association adopted a Memorandum outlining a National Maternity Service Scheme for England and Wales A little later the Departmental Committee on the Training of Midwives in its report suggested the establishment of a national maternity service broadly upon the same lines The Government took no action in regard to these proposals preferring to wait for a report from another Departmental Committee—that on Maternal Morbidity and Mortality—which was then sitting An interim report by that committee was published at the end of last July, and was described and commented on in the *Journal* of August 9th (pp 218 and 223) In that report, too, the establishment of a national maternity service was recommended as essential to a complete and effective effort to reduce maternal mortality and morbidity the principles and conditions of such a service followed precisely those which had been laid down in the British Medical Association's scheme, and the details of the service described kept even closer to the provisions of that scheme than did the proposals of the earlier Departmental Committee There has since been a powerfully supported public demand that a national maternity service on these lines should be established by legislation as soon as possible

The attitude of the Minister of Health towards these schemes and this demand has not been unsympathetic, but it is obvious that the political and economic exigencies of the present national situation do not make any Governmental legislative action easy In these circumstances the Minister, in several recent announcements made it clear that the immediate policy of the Government in this matter was to urge, and if necessary to enforce, upon local authorities a fuller use of the powers they now possess rather than to establish at once any more comprehensive service In a leading article in the *Journal* of November 15th last (p 831) we stated that there could be no serious objection to this policy provided that certain conditions were fulfilled These conditions were four in number (1) that when any further ante-natal clinics are established and in connexion with any extension of the work of existing clinics the local general practitioners shall be fully utilized for such work, so that practitioners who are liable to be called in at the confinement itself may be those who have knowledge of and responsibility for, the patient during pregnancy (2) that arrangements for specialist consultation and service whether ante-natal or at the time of the confinement or thereafter, shall be made with part-time consultants (3) in general, that no provisional arrangements shall be made which would interfere with the early establishment of the complete service, and especially that nothing should be done to prevent the linking of maternity work with a national insurance system, and (4) that negotiations shall be at once begun with all those concerned in the establishment of a national maternity service so that the settlement of the difficult financial and administrative questions involved may be facilitated

In pursuance of his declared policy the Minister of Health has now issued to all maternity and child welfare authorities a Memorandum (Memo 156/M C W) and an accompanying Circular (1167) drawing the attention of those authorities to the interim report of the Departmental Committee on Maternal Mortality and Morbidity reminding them that the development of the maternity and child welfare services is one of the conditions on which the amount of Exchequer grants depends, and setting out in some detail the directions in which, and the methods by which, such development may most suitably be undertaken It is a matter of great gratification to be able to say that the suggestions and requirements of the Minister stated in these documents seem to fulfil all the conditions set out above in accordance with the policy of the British Medical Association The Minister here declares that "the Government have decided to undertake the necessary negotiations with the various authorities concerned with a view to formulating a scheme on a national basis for the care of maternity which would provide the services suggested", and the immediate recommendations of the Memorandum are such as should present no real obstacle to the development of an appropriate scheme, which should promote a much closer association of local private medical practitioners with the work and encourage their active participation therein

The Memorandum emphasizes the conclusion of the Departmental Committee's interim report as to the four primary avoidable causes in regard to maternal mortality —namely, absence of ante natal care, errors of judgement in practice, lack of reasonable facilities for effective medical care and neglect to carry out the medical advice offered It is divided into six sections suggesting action with regard to (1) ante-natal services, (2) supply of midwives, (3) consultants (4) hospital beds, (5) provision of ancillaries, such as sterilized outfits home help , and milk supply, and (6) education The main portion of the Memorandum is appropriately devoted to the first of these

Ante natal Services

The twofold functions of the ante natal clinic—that of medical supervision on the one hand and educational and social work on the other—are clearly set forth Educational propaganda with regard to the need for ante-natal care is strongly recommended, and in this connexion it is stated that 'it will be essential to secure the co-operation of the doctors and midwives practising in the area, and of suitable voluntary organizations concerned with the welfare of women" The equally essential need for associating local medical practitioners with the supervisory function of the clinics is also pressed as follows

> The ante natal centre has however the obvious disadvantage that the doctor in charge of the centre seldom, if ever actually delivers the patient or is the doctor called in by the midwife in an emergency In some cases this disadvantage can be overcome to a certain extent by keeping the patient's doctor fully informed of the findings at the centre, but in many cases the medical officer of the centre is not aware of the name of the doctor who may attend the confinement It is therefore clearly desirable to encourage closer co-operation between the centre and the doctors practising in the area which it serves
>
> In the case of women who engage a doctor for the confinement the necessary ante-natal supervision will be undertaken by him, and in the case of women who are insured persons the insurance practitioner is responsible for medical attendance during pregnancy For these women the ante natal centre should be available for any additional care the doctor considers necessary But many uninsured women who engage midwives for the confinement are unable also to pay the fee of a doctor for ante-natal supervision and for such women the necessary provision should be made through the maternity and child welfare service

This can be done at an ante natal centre if it is reasonably accessible to the patients, and they are willing to attend there But in sparsely populated areas it is impracticable to provide centres within a reasonable distance of the homes of most of the women concerned and in towns there are many women who cannot be persuaded to attend the centres. In some rural areas the county councils are making arrangements with private medical practitioners whereby the latter undertake the routine ante natal examination of uninsured women who have engaged midwives for the confinement. Arrangements of this

kind might well be made by local authorities, not only in rural areas but also in towns, to meet the needs of those uninsured women who are reluctant to visit a centre for the purpose of ante natal examination

"It is suggested that a list might be prepared by the authority of those doctors practising in the area who are willing to undertake this service for uninsured women who engage midwives. The latter should be urged to explain to their patients the advantages of consulting a doctor during pregnancy, and, if they are unwilling to attend at the centre, encourage them to select one of the doctors on the list who should be the doctor to be called in by the midwife if any emergency should arise. The doctor should arrange to conduct the ante natal examination either at the patient's home or at his surgery, and he should be offered the facilities of the centre including the services of the nurse or the health visitor for the necessary following up of the case and subsequent supervision. In some cases arrangements might be made for the doctor to conduct the examination at the centre with the patient's consent. The midwife engaged by the mother should be kept fully informed, and encouraged to undertake as much of the ante natal care as she is in a position to do. It is essential that the full co-operation of the midwives should be secured, and it should be made clear to them that these arrangements are designed in their interests as well as those of their patients.

Experience has shown that unless ante natal supervision is adequately performed it may not only fail to benefit the patient but may even involve additional risk by giving her a false sense of security. Under the Local Government (Qualifications of Medical Officers and Health Visitors) Regulations, 1930, the medical officer of an ante natal centre is required to have had special experience of practical midwifery and ante natal work, and it is suggested that there are definite advantages in securing for these posts the part time services of private practitioners who possess the special qualifications prescribed by the Regulations. If possible facilities should also be provided for other doctors to see their patients at the centre if they so desire."

Similarly, in connexion with the provision of hospital beds, it is suggested that "local authorities should consider, wherever practicable, the desirability of affording facilities to private practitioners to attend their own patients in maternity institutions." All these suggestions as to the use of the services of private local practitioners and of facilities for such practitioners are of great moment. They are obviously in the interest of, and for the convenience of, the patient, and are absolutely essential if the full and hearty co-operation of the medical profession is to be secured. Without them, too, definite obstacles to the establishment of the desired national maternity service will be set up. There should now be vigilance on the part of the profession to see that maternity work is extended on these lines and on no others, and willingness to undertake the responsible duties suggested.

Strong support should be forthcoming for this forward move on the part of the Minister of Health, in accordance with principles and methods consistently advocated by the profession. The only doubtful point in the Memorandum with regard to medical services is under the heading of "consultants," where it is said "For any doctor who needs assistance in difficulties or complications arising during pregnancy, at or after confinement, it will generally no doubt be found desirable to engage the consultant at the maternity hospital or ante-natal centre serving the area." There are undoubtedly areas in which this will be found not to be the best or the usual, course.

In the section of the Memorandum regarding the supply of midwives some wise suggestions as to method are made, and here again the need for support for the privately practising midwife is not overlooked. Altogether, this is a most important memorandum, and the degree to which local authorities follow its suggestions will be watched with some anxiety.

CINCHONA TERCENTENARY CELEBRATION

CEREMONIES AT THE WELLCOME MUSEUM

A series of brilliant gatherings and learned addresses on the history and uses of cinchona have marked the celebrations at the Wellcome Historical Medical Museum of the tercentenary of the first recognized use of the bark by Europeans. The exhibition, which is to remain open until February, includes a wonderful collection of cinchona bark, and illustrates every phase of the subject. One of the exhibits is from the King of Spain, and shows three of the original seroons (containers made of straw, rushes or matting) of cinchona bark brought from Peru after an exploration in the year 1777. The Bolivian, Peruvian and Ecuadorian Consulates General have contributed, also several pharmaceutical and official bodies on the Continent while in this country the exhibition has been enriched by loans from the Imperial Institute, the Medical Research Council, the Pharmaceutical Society, the Royal Botanic Gardens, Kew, the Chelsea Physic Garden, several scientific societies and other bodies. Many tributes have been paid in the various proceedings to Dr. H. S. Wellcome, the founder of the museum, who has acted as host on all the occasions and whose special interest in the subject is derived from a visit which he himself paid fifty years ago, to the cinchona forests of South America. The catalogue of the exhibition, a beautifully bound and illustrated volume, is a choice souvenir of the occasion.

It was inevitable that in such a comparatively narrow field the subject-matter of the addresses on successive afternoons and evenings should cover much the same ground. This was specially so in the addresses delivered by Sir Humphry Rolleston and Sir David Prain, both of whom explored some of the curious byways of cinchona history and literature.

Sir Humphry Rolleston said that the British Empire with its far-spread extensions in tropical regions, had more than any other, great cause for gratitude for the discovery of cinchona and the subsequent isolation of quinine. He reminded his audience that malaria was far from being a vanquished disease. Recently it had been estimated that disability and loss due to malaria still cost the British Empire fifty-two million sterling annually, and ten years ago it was stated that in India there were 1,300,000 deaths annually from endemic malaria. The discovery of cinchona was one of the decisive victories of medicine and probably influenced Sydenham in coming to the conclusion that each disease should have its specific remedy. No other drug, said Neuberger, did so much to upset the current doctrines of medicine in Ramazzini's graphic simile it did for medicine what gunpowder had done for war. The present year by a coincidence was the fiftieth anniversary of Laveran's discovery of the malaria parasite.

Speaking of the early use of cinchona bark in England Sir Humphry Rolleston quoted advertisements which appeared in 1658—a year remarkable for the prevalence of intermittent fever—in the *Mercurius politicus*, one of which read:

"The Peruvian Bark, commonly called the Jesuites Powder which is so famous for the cure of all manner of Agues brought over by *James Thompson* Merchant of Antwerp is to be sold either at his own Lodging at the Black Spread Eagle in the Old Bailey over against Black and White Court or at *Mr. John Crooke's* Bookseller at the Ship in *St. Paul's* Churchyard with directions for its use. Which Bark or Powder is attested to be perfectly true by Doctor Prudjean and other eminent Doctor and Physitians who have made experience of it."

As for Sir Robert Tabor (or Talbor, or Talbot), the Court physician who did much to popularize the remedy in the time of Charles II, Sir Humphry Rolleston gave an account of his activities in France where he was sent to cure the Dauphin of the ague. The Dauphin recovering, Tabor received the title of Chevalier, a pension of £100 a year, and £2,000 for the secret of his "Englishmen's cure," which was an infusion of a considerable quantity of cinchona bark in good claret wine.

Sir Humphry Rolleston spoke finally of several alkaloids of which about thirty distinct kinds had been obtained from the bark, the most important being quinine, quini

dine, cinchonidine, and cinchonine. The various alkaloids differed from each other mainly in degree, the most powerful antiseptic was quinine but quinidine was the most effective in restoring the normal rhythm of the heart in auricular fibrillation and flutter. It had not yet been elucidated how quinine exerted its antimalarial action. There was something to be said in favour of the view that it acted on the parasites indirectly. Another view was that quinine favoured the production of antibodies. It had been thought to form a film on the red blood corpuscles, and so to prevent the entrance of the malaria parasite.

Sir David Prain, formerly director of the Botanical Survey of India and of the Royal Botanic Gardens, Kew, also gave an interesting historical review of the subject, and mentioned some modern work. He said that since the war much had been done in the study of the relative value of the various individual alkaloids contained in cinchona bark. When quinine was isolated in France in 1820 the two barks most in favour with French pharmacists were the "grey" and the "yellow", the latter must have been the material on which the work was done. Sir David Prain said that the cinchona bark recognized in the *London Pharmacopoeia* of 1677 was clearly the crown" bark of Loja the forest district of Southern Ecuador from which cinchona bark was first introduced to European medicine. No other bark was known to be used in England until a century later when "red" bark found its way to this country and met with much favour. Past experience indicated that at least up to 1820 the crown" the "yellow" and the "red" barks were all equally efficacious when used by competent authorities, and that "grey" bark which did not happen to contain quinine was as valuable as any of the three kinds which did yield that alkaloid.

An interesting address from a different point of view was delivered by H. E. The Marquis de Merry del Val the Spanish Ambassador, who claimed that the actual discovery of the efficacy of this wonderful medicine was due to a Jesuit missionary who was cured by its use of an attack of malarial fever in the province of Loja. He made known the remedial properties of the bark among the Spanish settlers, and in Europe the Jesuits, at that time in the zenith of their glory, introduced the newly found boon to ailing humanity.

Perhaps we may be allowed to add the remark made by the representative of a South American Consulate in one of the supplementary speeches. In his delightful English he declared that "quinine has made the world safe for malaria."

THE SURGEON'S WORK ON A POLAR EXPEDITION

In a paper on this subject read before the Sheffield Medico-Chirurgical Society Dr. A. H. MICKLEY said that the most important part of the surgeon's work lay in the preparation which was done before the party left England. The purely medical work consisted chiefly in examination of the personnel and in the collection of the equipment. The latter was likely to vary with the individual surgeon, the personnel the scope of the expedition, the stowage space and the finances.

Scurvy, Frostbite, Snow-blindness

Scurvy, frostbite, and snow-blindness were conditions common to all Polar explorations though rarely met with in home practice. A dissertation on these matters was no part of his lecture, other than to emphasize their great practical importance. There had been much discussion as to the cause of Captain Scott's failure and death, but in the history of that famous return journey from the Pole was a beautiful clinical picture of the onset and development of scurvy. Scurvy predisposed to frostbite, which, unless treated promptly and effectively, resulted in death of the part. Every effort had to be made to ensure that if gangrene set in, it should be the dry and not the moist type. Treatment was best carried out by the application of body heat, followed where necessary by warm dryness. Snow-blindness was really caused in Polar regions by dull diffuse light, on a bright day hummocks and ridges cast deep black shadows, and could be distinguished without effort whereas in diffuse light the whole area became a homogeneous dull white in which details could not be picked out, and men would stumble over lumps and pressure ridges without seeing them. In such conditions snow-blindness set in rapidly. Snow goggles, which cut out the ultra-violet rays, were only effective if the sides were protected also. The symptoms were marked conjunctival congestion, lacrymation, and photophobia, circumcorneal injection pointed to a deeper involvement. The condition was very painful. Relief could be obtained by use of zinc sulphate and cocaine, but even the mildest case lasted for days. There was no need to emphasize the disastrous effects of these three conditions on a party working under Polar conditions. They were all preventable. Careful collaboration between the leader of the expedition and the surgeon was required as to proper food and clothing. Well-fitting snow goggles were essential.

All the hands in addition to their own special jobs had to be prepared to take part in the general work of the expedition. The lecturer served not only as dog-driver and veterinary surgeon, but also was required to help work the ship on deck aloft, in the holds, in the bunkers and to take turns at being "Peggy" for the day which meant doing all the odd jobs such as scrubbing floors, helping the cook and washing dishes.

Experiences with the "Endurance" Expedition

A number of slides illustrating the actual conditions under which the surgeon would carry on his work were shown, and the course of the *Endurance* expedition was described. On the way to the ice the care of the sledge dogs was an important problem which raised the question of sanitation this was effectively dealt with by the institution of a permanent "watch". Entering the cold air of the Antarctic both men and dogs improved in health developed huge appetites, and put on weight. The *Endurance* having penetrated 1,000 miles of pack ice was beset and frozen in. There she remained imprisoned all through the long winter night of three and a half months. There was plenty of work for all hands food was good and plentiful and everyone remained cheerful and healthy. There was a liberal issue of tobacco, but no alcohol, except a small "tot" on Saturday nights.

The great spring blizzards caused the ship to be destroyed by the pressure of the ice. The party twenty-eight all told, had then to live on the floe where they remained seven months on a very short ration composed chiefly of meat obtained by hunting for seals and penguins. The flesh was dark red of coarse fibre and had a strong oily taste. The meat diet caused constipation, and troublesome fissures developed as the result of lack of sanitary and toilet facilities. The break-up of the floe involved an arduous and exhausting boat journey, during which the chief difficulty was thirst. Elephant Island was reached with many of the members suffering from frostbite, sea-water boils and various injuries. Shackleton set off with a boat's crew to make South Georgia and send relief. In getting this boat launched all those who remained were thoroughly soaked with sea-water. There was no spare clothing, a blizzard had destroyed the tents, sleeping bags were wetted through the party was houseless and the outlook at this period very black indeed. It was the only time the lecturer himself despaired of life. They were compelled to live under upturned boats. Food was a hand to-mouth business—seal, penguin sea birds, limpets and seaweed. Scurvy did not appear. Frostbites were frequent, and an operation for spreading gangrene had to be carried out on one of the party. Cessation of blizzards and finer weather effected an improvement, and life became more normal. Rescue which was expected in three weeks did not arrive for four and a half months when all hands were picked up alive. On arrival in civilization they were dirty not having washed for eleven months, but free from vermin, and the skins were in excellent condition. They had lost their immunity to bacterial infections, and all suffered from severe colds.

RESEARCH AND PROTOZOOLOGY

THE science of protozoology is concerned with free-living as well as parasitic organisms, and while the study of the former is of interest mainly to the biologist, it is the habits of the parasitic species which make it so important to the medical man. This is obvious when one recalls that within its purview are included the causal organisms of malaria—one of the greatest of the four great Captains of the Men of Death—of sleeping sickness, of kala-azar, of several of the dysenteries, and various others.

While it is true that the earliest unicellular parasites seen were protozoa—Leeuwenhoek discovered the intestinal flagellates in 1676—the impetus given to bacteriology by Pasteur and those who followed him rather overshadowed protozoology. Until Ross, at the inspiration of Manson, delved into the mysteries of malaria and the mosquito, until Bruce studied the trypanosomes and the tsetses, and until Theobald Smith, in the veterinary world, unravelled the tangled skein of Texas fever and the ticks—not till then did the science start to come into its own. It became a major factor when tropical medicine became important, and its study has advanced simultaneously with the development of the Tropics. It has progressed through the usual channels of evolution of a biological science. The earlier workers were concerned with morphology, classification, and life histories. As the group became better known, its members were pressed into the service of many of the various branches of biological study—genetics, sex physiology, evolution, ecology, and so on. It has now reached its adolescence, however, and a survey of the literature shows that, although many new species are being discovered each year, the trend of investigation is towards experimental work, and much time is being spent on the study of artificial development and culture of the parasites, on immunity, and on the complex host parasite relationships. But because animals are always more difficult to study than plants, and because the diseases caused by animals are tropical rather than temperate, the progress has been relatively slow, and the workers relatively few. It is now being realized that it is not always necessary to go to the Tropics for the material necessary for study, and that the comparative method which has already proved its value in other branches of medicine, can be usefully employed here also. The parasites of our common laboratory and domestic animals are little understood, and problems of the greatest scientific importance can be studied with them and. In special cases, of course, it is still necessary to obtain species from the Tropics, but much useful work can be accomplished with temperate forms.

In these circumstances many new workers are being attracted to the field from various branches of life—zoologists, medical men, veterinarians, hygienists, and sanitarians. Their interests are diverse, and the already considerable literature is scattered. To assist in correlating these interests, and in bringing together the important parts of the experimental literature, Hegner and Andrews have just published a small encyclopædia on a new plan, called *Problems and Methods of Research in Protozoology*.[1] Written in forty-two chapters, by twenty-seven different authorities, it is intended alike for the seasoned investigator and the embryo research worker. It opens with a general introduction on the host parasite relations between animals and the protozoa, it goes on to discuss the various groups, their different methods of cultivation and transmission, their serological reactions, the methods of studying the various problems, and concludes with lists of books and journals on protozoology and references to important papers. It makes little attempt to deal with morphology, taxonomy, and life cycles. That has been done most satisfactorily in Wenyon's already classical *Protozoology*, and, on a more restricted scale, in Thomson and Robertson's *Protozoology for Medical Men*. The new book may be regarded as a supplement to these and is intended rather for the laboratory than for the classroom or study. It is well written, and should present no difficulties to the beginner in the field.

Britain has always held a front place in medical research. Her tropical possessions and interests are the greatest in the world, and it is therefore the more regrettable to find that much of the modern work in the fundamental sciences of tropical medicine is being undertaken outside her borders. Imperial problems occupy now a more prominent place in her thoughts than ever before, and her legislators are awake to the fact that a healthy, disease-free people is the first essential in the development of a tropical empire. The opportunities for successful and satisfying work in the fundamental problems of parasites and their vectors are greater to-day than they have been since Sir Patrick Manson and Joseph Chamberlain established modern tropical medicine. Yet the number of young workers in the fields of medical protozoology, helminthology, and entomology is regrettably small. The practice of tropical medicine is proceeding apace, and Britain has no need to be ashamed of the numbers of her sons and daughters who are working in that field abroad. But the advance of medical practice depends in huge measure on the application of discoveries made in the laboratory, and workers there are just as essential as in the field and the consulting room.

THE SURGEON AS A HANDICRAFTSMAN

ETYMOLOGICALLY this heading is redundant, for the word "chirurgeon" originally denoted one who worked with his hands. It came into use in the days when the learned physician delegated the base mechanical parts of his work to an inferior and less erudite person. Practical surgery is still something of a mechanical art, but now that the surgeon combines in himself the physician who diagnoses the disease and prescribes the cure and the craftsman who carries out his orders, the hand has to be controlled and directed by the highly trained brain. Of late years it must have occurred to many to ask themselves how far the development of machinery of various sorts, and especially of electrical machinery, has affected the handicraft of surgery in the sense of making it less a skilled craft than formerly. Surgery is by no means singular in being affected by this development. All sorts of handicrafts have been modified by the progress of invention. The fitter, who in former times laboriously cut his way with cold chisel and hammer through steel plates now has but to direct the nozzle of an oxy-acetylene

[1] *Problems and Methods of Research in Protozoology*. Edited by Robert Hegner and Justin Andrews. New York: The Macmillan Company. London: Macmillan and Co. Ltd. (21s. net.)

pipe and watch it dividing solid steel as a hot knife through butter The enterprising burglar has been slow to follow his example Even in such h laborious occupations as paving and street uring the passer by no longer stands entranced to *ch the wonderful rhythmic co ordination of three* our athletes driving a wedge with sledgehammers iout faltering or missing a blow he now flees as and as far as he can before the awful ear ttering jar of the pneumatic drill or chisel Most hanical improvements lighten the labourer s task diminish his sufferings But we question whether vibratory massage transmitted to its holder by the umatic chisel is as wholesome as the free play muscles and joints enjoyed by the wielder of the ge and in fact several kinds of injury or illness now known to be related to the occupation of umatic drilling [1] All that can be said for it is that ves time

he armamentarium of the surgeon has in the last eration been enriched with a large number of hances and labour saving machines for use in nosis or in treatment Some of these require cial training for their successful manipulation and their turn have rendered possible surgical pro ures formerly impossible As a case in point we d only mention the bronchoscope Fifty years ago instruments used in operative surgery differed le in essentials from those employed by Ambroise e in the sixteenth century and probably were no ter than those in use in the Roman Empire at the ght of its civilization and refinement One of the st elaborate tools employed was the trephine in or other form with which laboriously and tiously the skull was opened The trephines resented in the *Dix Livres de Chirurgie* differ little m those in use until a few years ago Now how r electrically driven machines make the opening of cavity of the cranium and the removal of large ts of its walls a quick and easy proceed ng rtions of bone are expeditiously excised from healthy ts and implanted in others and these grafts are and their beds prepared by machines which ensure uracy and eliminate the danger from tired or un tain hands In an American journal not long since read an account of a method of reducing displace nt after fractures of the long bones by the use of a achine worked by electric power and this may prove harbinger of other developments yet to come

But when we reflect on the purposes for which these chanical aids are employed we find in most cases at the new machine is used almost entirely in new ocedures and herein surgery in a sense lags behind lustry The builder no longer relies upon the ourer with his hod of bricks toiling up a ladder t lifts them a thousand at a time by means of an ctric crane The steam or electric navvy has ousted human prototype in excavation but the surgeon io performs say *an amputation of the thigh* or a rnotomy does so with very much the same instru ents as his predecessors of a hundred years ago nesthetics have made it unnecessary for him to mulate the speed of Robert Liston—a speed only proached if it be not surpassed when the technique some modern operation is being demonstrated by ms of the cinematograph and arteries appear to ligatured and stitches inserted and tied at least as st as the eye can follow them leaving the beholder ondering again why time is not represented on the m as accurately as form

[1] See *British Medical Journal* December 13th 1930 p. 1013.

The bare hand of the surgeon is no longer tolerated in an open wound and even the gloved hand is looked on askance Indeed, it is only in what is pleonastically called manipulative surgery that the forceful but bare skilled hand of the surgeon still has it all its *own way The reduction of a congenitally displaced* hip is still achieved without the use of any but human machinery although even for this procedure something like the scammum of Hippocrates has been rediscovered and used by a few In the vast field of abdominal surgery too the machine has not ousted the skilled hand The *tactus eruditus* is here as necessary as ever, *and neatness and skill in the use of needle* and suture does not seem likely to be superseded by any sewing machine unless indeed another Howe springs upon us a surprise such as is at present inconceivable When all is said however we shall find that no matter how much mechanical devices are multiplied or elaborated it is the man behind the *machine that matters* whether he be using his bare or rubber gloved hands or the latest invented and most complicated electrical or pneumatic apparatus

TRAFFIC IN DANGEROUS DRUGS

THE first or preliminary conference on the limitation of the manufacture of dangerous drugs to which allusion was made in the *Journal* of September 27th (p. 535), was held in London from October 27th to November 11th A report has been submitted to the British Government for presentation to the League of Nations It will be remembered that at this preliminary conference only producing countries were represented There were nine in number and included three which are not members of the League—namely Soviet Russia Turkey and the United States The other participating Powers were Great Britain France Germany Netherlands Switzerland, and India The deliberations of the conference were private and the minutes of the proceedings are confidential From a reply given in the House of Commons recently it was to be gathered that the report of the proceedings has been sent to the Secretariat of the League of Nations that it is now in the course of being printed but that it is not possible to say *when it will be available to the public* A communique which was vouchsafed to the press on November 13th admits that no final decision was arrived at in regard to limitation and the allocation of production in the case of morphine and heroin while some agreement appears to have been provisionally approved in regard to the manufacture of cocaine Thus far the objects aimed at in the resolution passed unanimously by the Assembly of the League last September do not seem to have been attained nor has the ground *been adequately prepared* for the larger conference to be held next May in Geneva at which all countries producers and consumers alike will be represented The Assembly shocked by the magnitude of the illicit traffic requested the preparation of plans whereby the supply of dangerous drugs should be restricted to the amounts required for medicinal purposes If the conference to be held next May is as is *contemplated to draft* a new Convention to limit effectively the production of the drugs *in question to legitimate requirements* and apportion to each producing country its quota of manufacture, a great deal more preparation will be necessary than has so far been successfully accomplished It is reported that if each producing nation were allowed the quantity which its manufacturers deem appropriate the total would greatly exceed what is considered to be the world s needs The League of Nations has been advised that 250 tons of raw opium and 6 tons of cocaine are sufficient for the world s requirements ' The recent conference had the advantage

of the presence of a representative of Turkey a country which though a large producer of opium, has not hitherto seen fit to ratify either The Hague or the Geneva Conventions Turkish statistics have been published which suggest that from its factories large quantities of opium morphine, and heroin pass into illicit channels In the first six months of this year it is stated, 2,282 kilograms of morphine and 4 383 kilograms of heroin were exported, and that this last amount represents about forty times the amount of heroin consumed in Great Britain in a year It is not surprising that Soviet Russia's representative considered that the conference was working on too narrow a basis and that it should have included in its purview the limitation of the production of raw opium and of the coca leaf This question is, we understand again likely to be raised at the Geneva conference in May Seeing that The Hague Opium Convention of 1912 was designed to secure the suppression of the use of narcotic drugs, and to pledge its signatories to co-operation with one another to prevent their uses for other than medical and legitimate purposes, and seeing that all but ten nations are now parties to that Convention, it is amazing that progress is so slow, and that action on the lines prescribed by our Dangerous Drugs Acts of 1920–25 has not been more widely adopted

THE AFRICAN SLEEPING SICKNESSES

IN 1901 Forde and Dutton discovered *Trypanosoma gambiense* in the blood of man in Gambia, and a year later Castellani isolated the same organism from cases of sleeping sickness A second human species was recorded in 1910 by Stephens and Fantham under the name of *T rhodesiense* Various species had been found in the lower animals before this time, however Lewis, in 1878 had discovered the common almost non-pathogenic, species in rats and two years later Evans found that *T evansi* was the cause of surra in domestic animals in India In 1894 Bruce made his famous investigation on n'gana, and not only discovered *T brucei* but proved that it was carried by tsetse flies from animal to animal Since that date it has been shown that n'gana is caused by a variety of trypanosomes, but it is with *T brucei* that the medical man is mainly concerned This species occurs naturally in game and domestic animals in Africa, but while many attempts have been made to transmit it to man, all have proved failures Nevertheless it is morphologically identical with *T rhodesiense*, and differs from *T gambiense* only in minor details In the blood of man in fact, these two species appear identical, although the disease caused by the former is more severe In laboratory animals, however a small percentage of both *T brucei* and *T rhodesiense* have the nucleus moved to the posterior end of the body while in *T gambiense* it is always centrally placed In recent years, British authors have generally agreed in regarding *T rhodesiense* as a human strain of *T brucei* although they accept *T gambiense* as a separate species The question of the origin of these species has recently been investigated by Yorke, Adams, and Murgatroyd[1] and some very interesting discoveries have been made Human serum was found by Laveran in 1902 to have a definite therapeutic effect on mice infected with *T brucei* from cases of n'gana The English authors have now been able to show that normal human serum or citrated plasma exerts a pronounced trypanocidal action *in vitro* on *T rhodesiense* and other species, except *T gambiense*, and they believe that man's immunity to the various animal species is due to this property of his blood The lethal effect on *T rhodesiense* was surprising, and has caused them to formulate a new and interesting hypothesis on how human beings become infected They believe that *T gambiense*, like *T rhodesiense*, is identical with *T brucei*, its apparent greater differences being due to more profound modification, resulting from numerous passages through man The natural host of the organism is wild game, but the game trypanosome is not pathogenic to normal man because of the protective action of his blood Under certain conditions pathological and dietetic, the trypanocidal substance is destroyed, and he becomes susceptible If such a person is infected he develops a *rhodesiense* infection (which would be unlikely to assume epidemic significance) This occurs in regions where the predominant tsetse is *Glossina morsitans*, which feeds chiefly on game Where however, the predominant fly is *G palpalis* (which has a more intimate contact with man), an infection similarly developed would have a greater chance of being spread from man to man, and the prolonged passage would result in its acquiring a resistance to the trypanocidal action of human blood If this property is inherited—that is if it survives passage through the fly—the infection could spread from man to man through cyclically infected flies If not, then human epidemics must either be caused by mechanical transmission by the proboscis of the fly or by the existence of some local condition such as dietary deficiency or hookworm disease which would destroy the trypanocidal power of his blood When *T gambiense* is passed to game or domestic animals it quickly loses its serum resistance and becomes incapable of infecting normal man While this is still hypothetical, it is supported by many facts One of the most interesting of these is the recent accidental infection *of a laboratory assistant in Paris with T brucei* If this hypothesis is confirmed—and it can only be confirmed in tropical Africa—it may have a very great bearing on the methods of eradication and control of the disease Meanwhile, considerable interest has been taken in recent years in the chemotherapy of the disease and several new drugs have been introduced into practice with more or less satisfactory results Atoxyl has been very extensively used in the past but it is now being displaced by another pentavalent arsenical compound "tryparsamide," the sodium salt of n-phenylglycinamide-p-arsonic acid The name is a trade mark registered and controlled by the Rockefeller Institute for Medical Research It can only be manufactured under a strict licence in the interests of the public and the institute receives no profit whatever in connexion with the sale and manufacture of the drug A similar compound is marketed in Belgium though not under licence under the name "tryponarsyl" Tryparsamide was developed by the Rockefeller Institute in the first place, and has been used extensively during the past ten years for the treatment of sleeping sickness due to *T gambiense*, but clinical observations support the view that it has little curative value in the later stages, at least of Rhodesian sleeping sickness It has a high factor of safety in experimental animals and a high mortality to the parasites Recently it has been the subject of a monograph by Louise Pearce,[2] in which is given a detailed analysis of over a thousand cases She considers that it exerts a unique action on advanced cases but is equally satisfactory in early cases, and is vastly superior to any other drug yet used It is recommended for general use under the conditions of both lazaret and field administration Most drugs in use against trypanosomiasis—and this is equally true of those used against bilharzia disease—have the great disadvantage from the point of view of administration to natives that they must be given hypodermically and undoubtedly a drug capable of oral administration would be of benefit Bayer 205 and others have occasionally been given in this manner, and a new

German preparation called "4002" which has yet to be tested extensively in the field has given promising results in laboratory animals Research in this sphere is very active just now and soon we may be in possession of an ideal specific that can be administered by mouth

LEPROSY IN THE BRITISH EMPIRE

Two illustrations of the advance which is being made in the campaign against leprosy have been forthcoming recently In the annual report for 1929 of the British Empire Leprosy Relief Association an account is given of the way in which the administrative side of the campaign is being intensified and extended, with a corresponding rise in cost During the year Mr Oldrieve, who has been secretary of the association since its foundation resigned and was succeeded by Dr Robert Cochrane The second illustration is afforded by a useful booklet of seventy five pages embodying the fifth edition of Dr Ernest Muir's well known book *Leprosy Diagnosis Treatment and Prevention*[1] This booklet is an outcome of an undertaking given by the Central Committee of the Indian Branch to make itself responsible for the promotion of research and propaganda against leprosy As the research worker in leprosy at the Calcutta School of Tropical Medicine and Hygiene, Dr Muir has enjoyed special facilities for observing the progress of new discoveries He has now collated and condensed all the work achieved up to the present and has included the results of his own researches in order that they may be available for the use of doctors in India and elsewhere The fact of his publication having now reached the fifth edition is a proof of its usefulness, it evinces a commendable desire to keep the work up to date and to deal with the difficulties which doctors have in carrying out the therapeutical measures propounded Another problem which has received special attention is the production of hydnocarpus esters by hot and cold processes Dr Muir gives first place in treatment to creosoted hydnocarpus oil and its esters, which he describes as the most useful economical, and painless preparation He finds that sodium hydnocarpate which was advocated so strongly by Rogers is apt to cause endophlebitis and to block the veins when injected intravenously, he suggests, therefore a technique by which this can be avoided Sodium hydnocarpate is especially convenient in countries like Africa where hydnocarpus trees are not yet available, since it occupies little bulk and can be conveniently imported Dr Muir's booklet is packed with practical information It deals with the symptoms diagnosis, and the general principles of treatment and cannot fail to be most useful not only to doctors in India, but also in other countries in which leprosy is endemic Indications are given how the campaign against leprosy should be conducted The last Indian census taken in 1921 gave the total number of lepers as 102 513 but from subsequent surveys by expert medical officers there is good reason to believe that there are between four and five times that number infected A summation of all the work done in the study of leprosy emphasizes the importance of the removal of predisposing causes which lower the resistance of the patient to this disease The desirability of early diagnosis is very great since a relative cure can be obtained if the disease is taken in hand in the first stage but this becomes more difficult and requires an increasingly long course of treatment as the disease advances By the erythrocyte sedimentation procedure it is possible to test a large number of blood samples at once with fair accuracy and with the expenditure of a minimum of time this method has been proved to be most useful also in determining the degree of resistance Those in charge of leper institutions who may wish to prepare their own hydnocarpus esters will find in this book practical methods of technique which will put them in possession of the best treatment at very moderate cost Since all authorities on leprosy are now agreed that the sheet anchor of treatment lies in preparations from the seeds of hydnocarpus trees, the British Empire Leprosy Relief Association might well consider more carefully the desirability of further botanical research into the possibility of introducing these trees in British possessions in Africa where this disease is rife *H wightiana* and *H anthelmintica* grow in Southern India, Burma, Siam and China and there is an allied species, *Carpotroche brasiliensis* which abounds in Brazil The leprosy-affected regions of Africa lie, for the most part in the tropical zone and it is probable that hydnocarpic trees could also be raised there If so, this would place the question of treatment in Africa on a more economical and widespread basis The fresher the seeds, the more active is the therapeutic action of the oils obtained from them

SPINAL TUMOUR WITH SYRINGOMYELIA

A somewhat rare but practically important type of spinal tumour forms the subject of Dr Jonesco-Sisesti's book on tumours of the spinal cord associated with a syringomyelic condition[1] Nineteen cases are described, three of which came under the author's observation, the remainder being drawn from the literature The author's attention was called to the condition by certain cases under Professor Guillain in the Salpetriere in which the clinical syndrome appeared to be clearly that of spinal compression, whereas laminectomy revealed an inoperable intramedullary tumour An anatomical examination of these cases showed that in addition to a localized central tumour there was also present a diffuse gliomatous formation which extended for a variable and sometimes great distance above and below the tumour and exhibited the cavitation familiar in syringomyelia The association of the two lesions produces certain clinical symptoms which, with an examination of the cerebro-spinal fluid and exploration with lipiodol, render a diagnosis possible This type of case being inoperable resort was had in one instance to radiotherapy, applied widely beyond the limits of the tumour The patient, a male aged 16, was admitted to the Salpetriere with paralysis of both upper and lower limbs and extensive muscular atrophy A laminectomy revealed the presence of an inoperable tumour in the cervical region After a series of eleven irradiations the atrophy of the quadriceps extensors had disappeared and the power both in the extensors and in the flexors of the thigh was almost normal In the upper limb there was partial recovery of strength on the left side On the other hand the area of superficial sensory trouble had apparently increased in extent A second series of irradiations applied a few months later, was followed by further amelioration The patient was able to walk without assistance considerable power was regained in the upper limbs and the sensory troubles had almost entirely disappeared The amelioration persisted for the three years during which the patient was under observation One must assume that in this case the gliomatous formation was reduced by the irradiations and if the tumour was of the same nature it is probable that it would also have been affected It is doubtful whether tumours having a different structure would be influenced, but these also may be associated with a widespread gliomatous formation, and symptoms referable solely to this condition would presumably be ameliorated by irradiation Has irradiation, as applied to the spinal cord in cases of tumour, any disadvantages The records under this heading refer mainly to extramedullary tumours Cases have

[1] *Tumeurs Médullaires et leur Traitement par la Syringomyélie* Par N Jonesco-Sisesti Paris Masson et Cie (45 fr.)

been reported in which this treatment has been followed by permanent exaggeration of the pains and sometimes sudden exaggeration of all the symptoms, with transformation of flaccid into spastic paralysis, and even acute decubitus—accidents apparently depending on vasomotor changes leading to serous exudation or haemorrhagic extravasation

A HISTORY OF MEDICINE IN MASSACHUSETTS

As this year is the tercentenary of the settling of the Massachusetts Bay Colony, and next year the hundred and fiftieth anniversary of the founding of the Massachusetts Medical Society will be celebrated, Dr H R Viets, a Fellow of that society, appropriately supplies *A Brief History of Medicine in Massachusetts*,[1] which sketches the events from 1620, when the pilgrims landed at Plymouth, up to the present day, thus supplementing Dr Samuel H Green's work which appeared in 1881 The Pilgrims obtained their medical advice from clerics also possessing a knowledge of the ills of the body, especially from Deacon-Doctor Samuel Fuller, who died of small-pox in 1633 After this there was not any prominent medical man in Massachusetts for nearly a century, and medical practice was carried on by several classes of people by the governors of the State, especially John Winthrop the Younger (1606–76), a correspondent of Sir Kenelm Digby and a Fellow of the Royal Society, by barber-surgeons, clergymen, and others, some with, some without, medical degrees Thomas Thacher (1620–78) was the outstanding Puritan preacher-doctor of his time, and in 1677 printed a "Brief Rule" of advice about the "Small Pocks, or Measles" Another doctor-preacher, Giles Firmin, educated at Emmanuel College, Cambridge, was probably the first anatomical lecturer in America In the eighteenth century epidemics of small-pox were frequent and were to some extent modified by direct inoculation, introduced in 1721 by Zabdiel Boylston and advocated by Cotton Mather, but it was not until Benjamin Waterhouse initiated Jennerian vaccination in 1800 that any well-marked decrease in the death rate followed In 1735 a medical society, the predecessor of the Massachusetts Medical Society established in 1781, was started and lasted about five years Boylston's rival, William Douglass, who opposed inoculation against small-pox, was the leading physician in Boston about 1750, and was a keen supporter of the medical society James Lloyd had an outstanding position as an obstetrician, and instilled into the younger men the teaching of the two Hunters and Cheselden The achievements of the Warrens and of James Jackson (of whom a striking portrait is given) are dutifully recorded, and the influence of the teaching of Louis in Paris is noted The activities of Oliver Wendell Holmes, the Bowditches, and Jacob Bigelow rightly find a place, a chapter is devoted to the discovery of ether anaesthesia, and finally G R Minot and W P Murphy's work on the liver treatment of pernicious anaemia is entered in this Valhalla of Bostonian medicine

EDUCATION FOR SCIENTIFIC INDUSTRY

"It may well be questioned whether the school education of to-day is a satisfactory one for the lad who intends to devote himself to either science or productive and progressive industry Two totally distinct subjects have here to be considered—namely, education and instruction Education consists in expanding the powers and resources of the mind, whilst instruction consists in filling it with information, it is more easy to instruct than to educate" With these remarks, made in the course of the Norman Lockyer Lecture delivered recently before the British Science Guild,[2] Sir William J Pope, who had taken for his subject "Science and modern industry," turned from his survey of the new political outlook, demanded and to some extent created by scientific industry, to a consideration of the educational problems that are peculiar to this era Modern industry, he reminded his audience, is so scientific in character that early education in science would seem to be excellently calculated to fit young men to take up an industrial career He soon made it clear, however, that by the term "education in science" he meant something very different from the application of a cramming system to young receptive minds, sating them with detail, but giving them no real understanding of general scientific principles He repeatedly found young men entering the university equipped already with a sufficient knowledge of theoretical organic chemistry to see them through the honours degree examination they were to take some years later But these young men, laden with notes on all matters about which examiners might be expected to ask questions, were weary of science, poorly trained in laboratory work, and lacking in general education Only rarely were any found among them who could read foreign languages with ease, and still rarer were those who could understand a spoken foreign tongue It is possible, suggested the lecturer, that we have passed too rapidly and unsystematically from the classical and mathematical education given in our higher schools up to fifty years ago, and have lost something essential in the process Certainly a thorough training in the intricacies of Greek grammar was a splendid mental discipline, it exercised the memory and quickened the intelligence The older school teachers never tried to make a subject easy, realizing that the more difficult the task the greater was its educational value, and that only when it was desired to instruct rather than to educate was it legitimate to make the operation as easy and painless as possible Sir William Pope explained, however, that he was far from advocating a return to the classical and mathematical education of former days Natural science, he said, offered a mental discipline far more stimulating than the study of a dead language, but it was essential that the schools should know exactly what they were at when they provided so-called scientific education, that they should inculcate the broad principles of the natural sciences and methods, and provide liberal courses of practical work in the laboratory "It must be conceded that our present-day English school system, the most expensive in Europe, calls loudly for revision, modern science and modern industry demand recruits who have received a liberal education Much has to be undone and redone when the schools send to the university or to the industries young men who cannot express their thoughts grammatically in writing, but who are stuffed with facts relating to highly specialized branches of science"

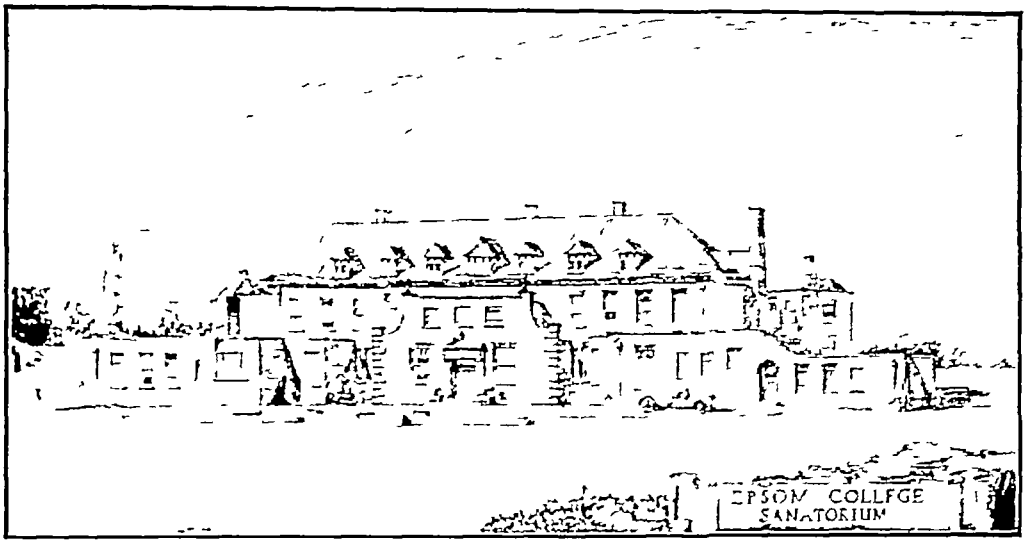
THE Medical Research Council announces that it has awarded three Dorothy Temple Cross Research Fellowships for 1930-31, these being the first appointments to be made under the terms of the recent benefaction in that name for research fellowships in tuberculosis, as follows Arthur Ivan Granville McLaughlin, M B, Ch M, chief assistant, tuberculosis department, St Thomas's Hospital, London, Reginald John Matthews, M D, D P H, D T M and H, chief tuberculosis officer, Mid Glamorgan area, and medical superintendent, Cymla Hospital, Sidney Malcolm Burrows, M R C S, L R C P, Lieutenant R A M C, attached Sudan Defence Force Dr McLaughlin has received a Fellowship for the study of methods of diagnosis and treatment at some chosen centre in the United States Dr Matthews and Lieutenant Burrows have received Senior Fellowships, and will make special studies of problems of tuberculosis among the native populations in Zanzibar and in the Bahr el Ghazal province of the Sudan, under arrangements made by the council with the respective Governments.



EPSOM COLLEGE SANATORIUM

THREE years ago there was published in the *British Medical Journal* an account and illustration of the sanatorium which it was proposed to erect at Epsom College, and an appeal was opened for the necessary funds. In our advertisement columns this week particulars are given of the revised plans for this sanatorium, the building of which has already started. The illustration on this page shows the north front. It will be at once apparent that certain changes have been introduced into the original scheme.

By designing a three-storey, instead of the two-storey, building previously contemplated, the architects (Messrs. William A. Pite, Son and Fairweather) have been able to provide accommodation for the patients on the ground and first floors with considerably increased floor space for each bed. There are also more bathrooms and sanitary annexes, arrangements having been made for the housing of the staff on the second floor. The positions for the operating room and x-ray room have been reversed, the first being now situated in the out-patient wing, and the second near the entrance hall—a much more satisfactory arrangement. These, and certain other changes, have been introduced as the result of friendly constructive criticisms made during the period while sufficient money was being collected to finance the building.

The new site selected is over a quarter of a mile from the main road and away from the noise of traffic—a considerable boon to both patients and nurse. The sanatorium will be heated by low-pressure hot-water radiators, but provision has been made by which they can be converted at any time to electric convection radiators should this appear to be economically advisable.

The contract of Mr. E. H. Smith of Croydon for the erection of the sanatorium has been accepted, and the actual work began on October 16th. The contract price is £26,245 for a fifty-bed sanatorium, and by the terms of the agreement the building is to be completed in June, 1931. This will allow the late sanatorium to be converted to its new use as a house for fifty boys by the beginning of the Michaelmas term next year.

EPSOM COLLEGE SANATORIUM: PROSPECT FROM THE NORTH WEST.

TREATMENT OF EYE CONDITIONS IN INDIA.

BY

E. R. SHETTI, L.C.P. AND S. BOMBAY,

MEDICAL OFFICER IN CHARGE OF THE HENDERSON EYE INSTITUTE, CIVIL HOSPITAL, BIJAPUR.

THE following are some of the methods of treatment carried out at the Henderson Eye Institute, the ophthalmic branch of the Civil Hospital, Bijapur, Bombay Presidency. I have confined myself to conditions that occur commonly in this district and of which the ophthalmologist in India is able to acquire considerable experience.

Keratomalacia with Xerophthalmia

This disease is very common in the Bijapur district and in Southern India in general. Its prevalence is due to ignorance of feeding and rearing babies, most of whom get a wrong diet. Deficiencies in the essential food elements during fever and other illnesses cause weakness and emaciation. Diarrhoea sets in and gets worse day by day. The first evidences of keratomalacia are night blindness and dryness of the part of the cornea and conjunctiva exposed in the palpebral aperture. Lustre of the cornea and conjunctiva is diminished, slowly a haze of increasing density forms over the cornea, and advances to ulceration, sloughing, perforation, and even to panophthalmitis.

The prognosis of these cases if they arrive early is most promising. A dose of santonine is first administered and often a lot of worms pass. The eyes are treated with instillations of drops of pure cod liver oil daily and dionin occasionally, and a little yellow ointment, a pad and a bandage. Fever and diarrhoea are met with quinine and astringents. Milk injections, 1 to 3 c.cm. for children below 5 years, are given intramuscularly once in four to six days to stimulate leucocyte formation and phagocytosis. Cod liver oil is rubbed on the whole body especially to parts like the abdomen, axilla and groins. The patients are fed on albumin water and thin milk mixed with lime water. By this treatment many early cases are cured.

Trachoma

These cases are common. We touch the everted lids with copper sulphate solution 10 per cent. once daily. For flabby and prominent granulations expression with Knapp's roller forceps and brushing with 10 per cent. copper solution in glycerin is the routine treatment. The eyes are then daily washed with mercuric chloride lotion and argyrol, and yellow ointment is put in. When the inflammation subsides—that is, after about a week or ten days—1/2 to 1 c.cm. of 1 per cent. solution of copper sulphate with novocain is injected

underneath the conjunctiva just behind the tarsus, and the injection is repeated once a week for three or four weeks This treatment has met with success in many cases

Glaucoma

Glaucoma cases are treated first with eserine and adrenaline and then submitted to operations—iridectomy for acute, and trephining (sclero corneal) for chronic cases For very high tension an intravenous injection of sodium chloride solution 1½ per cent is given up to about half a pint at a time This reduces the tension and enables trephining to be done safely

Trephining with Iridectomy

Trephining with iridectomy is often done for staphyloma of the cornea in cases where the cornea is not much thinned By this method a big segment of iris can be removed and staphyloma reduced For a large staphyloma with thinning of the cornea nothing short of enucleation is of any use Trephining with iridectomy is also successfully done for adherent opacity of the cornea where the anterior chamber is very shallow and is in close contact with the back of the cornea In these cases the usual optical iridectomy often fails, as the iris lies close to the cornea and iris forceps fail to bring any portion of iris out In such cases sclero corneal trephining brings up a segment of iris in the wound and iridectomy can be performed easily

Recent Staphylomata

Recent staphylomata are often treated successfully with continued use of eserine, dionin, adrenaline chloride, and pressure bandage On reduction of the staphyloma iridectomy or trephining with iridectomy is done for restoration of vision

Cataract

Both methods (intra and extra capsular) are adopted according to indications During the past year there has not been a single case of iris prolapse or of sepsis or of large escape of vitreous By washing the eyes with mercuric chloride 1 in 6,000, before and after cocaine anaesthesia, sepsis has been abolished from the Eye Institute during the last ten years The canthus is generally split to enlarge the palpebral aperture and minimize the danger of squeezing As B P Banaji says, "It gives a broader field for operations, lessens the squeezing power of the lids, drains away the conjunctival fluids, and lessens the chances of the instruments becoming contaminated by coming in contact with lid borders, and it is absolutely free from any bad effect"

Corneal Ulcer

Ulcers of the cornea are successfully treated with atropine and bandage, silvering of the lids also being done for some days, as these ulcers are generally due to conjunctivitis Septic ulcers and hypopyon ulcers are cauterized with camphor and carbolic (equal parts of camphor and carbolic), and paracentesis of the anterior chamber is repeated as required A few iodine injections intravenously hasten the cure

Fundus Cases

For papillitis, retinitis pigmentosa, and optic atrophy or optic neuritis, besides treating the root cause, such as syphilis, septic tonsils and pyorrhoea, iodine injections (1/2 grain pot iodid and 1/2 grain iodine in 10 c cm distilled water) are given intravenously once every three or four days till about six injections have been made Mercurial ointment for rubbing into the temples daily, and deep cyanide injections (cyanide of mercury 1 in 2 000 with novocain) 1/2 to 1 c cm once in about eight days are given Many cases have progressed markedly on this treatment and a notable feature is the rapidity with which the vision often improves after one or two intravenous iodine injections Where there are no prominent veins the following is given intramuscularly sodium iodide 250 grains, iodine 200 grains ac carbol liq 3 drachms, aq dest 4,000 c cm Of this 10 c cm are injected into the muscles (preferably gluteal) every six or eight days The mixture should not be stirred

I am greatly obliged to the civil surgeon and chairman, Blind Relief Association, Bijapur, for permission to publish this note

Union of South Africa.

[FROM OUR CORRESPONDENT IN PRETORIA]

Antimalaria Measures

DURING the past two summers outbreaks of malaria of epidemic proportions have occurred in Natal and Zululand Last summer the disease reached areas in Southern Natal, which had not been affected for the two previous decades Although this outbreak was less virulent—accounting for 1,653 recorded deaths, compared with 2,758 the previous year—it has had a disquieting effect, and demands for direct Government action have been made in the lay press and elsewhere The idea is prevalent that the central Government should itself carry out drainage of privately owned land and other measures to combat future outbreaks To clarify the position, the Union Health Department has issued a memorandum on the subject, in which it points out that owners and occupiers of land are responsible for carrying out measures against mosquitos and malaria The Government is not prepared in any way to relieve them of such responsibilities and thereby improve localized areas of land at the cost of the general taxpayer It is, however, carrying out active investigation with a view to advising private owners and local authorities as to the best and most economical methods of dealing with the malaria danger Last summer it employed two medical officers, five inspectors, and a large number of European and native assistants to make malaria and mosquito surveys, and to advise owners of land and local authorities The native assistants proved most useful They had previously received an intensive course of training from the malaria medical officer, which included diagnosis of the disease, the recognition of mosquito carriers and their larvae, and the methods of destroying the larvae They kept in close touch with the native population, investigating suspected outbreaks and reporting them to the magistrates of the district The attitude of native chiefs varied Many showed great interest and readily co-operated, others were indifferent and even hostile

Malaria Investigations

During the following winter Sir Malcolm Watson, principal of the department of malaria control, Ross Institute, London, who was investigating malaria on the copper fields of Northern Rhodesia, was invited by the Union Government to visit and report on the worst malarial districts Accompanied by Dr Annecke, Government malaria officer, and Mr de Meillon, entomologist to the South African Institute for Medical Research, he investigated during June last the conditions in the malarial areas of the Transvaal, Zululand, and Natal In addition to his field investigations, he did useful propaganda work, giving several public lectures He took an optimistic view of the possibility of malaria control in the Union, emphasizing the necessity of a vigorous campaign based on further scientific research Such research, he said, must include the study of the malaria-carrying mosquitos, their breeding grounds, and bionomics generally, and spleen surveys of the human population in affected areas The Government's next step was to secure the services of Professor N H Swellengrebel of the Amsterdam University to study the problem in the two affected provinces of the Union, Transvaal and Natal, and to advise and assist in framing an effective antimalaria policy, based on the scientific study of the problem on the spot Professor Swellengrebel landed in South Africa in October, and has started a preliminary general survey of the affected regions On these tours he is being accompanied by the malaria officer of the Union Health Department and the entomologist of the South African Institute for Medical Research Professor Swellengrebel, who is a member of the Malaria Committee of the Health Organization of the League of Nations, is a distinguished entomologist and protozoologist His work in the field of tropical hygiene is well known, especially with reference to plague, dysentery, and malaria

Leprosy in South Africa.

Although segregation continues to be the only practicable policy for dealing with leprosy in the Union, definite progress in the solution of the problem is being made. Until recently most cases of leprosy were in a fairly advanced stage and had been infective for a long time before they were reported and segregated in one of the institutions. This may have been due partly to the fact that acknowledged leprosy meant lifelong incarceration. With the policy adopted during recent years of liberating non-infective lepers on probation the horror, especially among the native population, of entering a leprosy institution is diminishing. Active propaganda in the native territories aimed at presenting these institutions in a more favourable light is having useful results, and voluntary notifications by lepers is now not uncommon. The natives are beginning to learn that if a leper presents himself at an early stage of the disease he has a reasonable hope of cure by taking advantage of the opportunities of treatment at the institutions, also that duration in the institution is not indefinite, and that institutional life—except for the breaking up of home life—is in many ways attractive. A result of this propaganda has been an increase in the annual number of admissions. According to the annual report of the Department of Public Health for the year ended last June 127 more natives were admitted than during the previous year. Bantu lepers treated during the two years numbered 648 and 521 respectively. This increase is due to the number of early cases that are now being admitted. The average period between the onset of the disease and admission is being shortened, with the result that progress is being made in reducing the large reservoir of undiscovered cases in the native territories. Another improvement in this respect is the increased efficiency in removing notified lepers. Depots for temporary detention of newly discovered lepers, pending removal to an institution, have been erected at various points in native areas, and the number of these depots is being increased. Motor ambulance removal of patients has already been arranged for one circuit, and it is hoped during the coming year to arrange similar services for other areas. A very successful publicity tour was carried out in one native district by five non-infective lepers from the Emjanyana Institution, who addressed meetings in several kraals and described the conditions prevailing in the institution. The result of the meetings was that several undiscovered lepers came forward voluntarily. The historic leper institution on Robben Island, off Capetown, is being closed down owing to the unnecessarily high cost of maintenance and to the fact that the climatic and other conditions of the island are unfavourable for leprosy patients. Since public opinion no longer demands the excessive degree of isolation suggested by an island, the patients are being transferred to the Pretoria Institution. It is expected that all the lepers will have been removed and the institution closed down by the end of next March.

Infection of Leper Official

Last June one of the medical officers of the Pretoria Leper Institution retired from the public service on account of having contracted leprosy. At the October meeting of the Northern Transvaal Branch of the Medical Association of South Africa (B.M.A.), which was held at the Pretoria Leper Institution, the patient himself gave an account of his early symptoms and observations.

In February 1929, while applying pressure in touching up the skin with the tip of a pencil, he noticed that the lipped end penetrated deeply into the leper's flesh. He at once pulled off the glove, squeezed the finger, and dipped it in tincture of iodine. The wound healed quickly, but the following May he noticed a discoloration and some anæsthesia at the site of the wound. There was also pain on pressure. The condition which he noticed was associated with the pricking incident progressed without attracting any great attention, but had become troublesome that he was obliged to use his middle finger for holding microscope slides. In February numbness and neuritic pains were experienced in both hands, and a small patch appeared on the left index finger. Deep ulceration of the original prick and elsewhere on the hand followed, and the ulnar nerve was swollen and tender. A similar patch appeared on the outer side of the right ankle, the left hand swelled up, the tips of the third and fourth fingers of the right hand became hyperæsthetic. Nasal smears were taken in February and subsequently, but no *B. leprae* have been found. In March the patient decided to have the finger amputated. The portions removed were examined at the South African Institute for Medical Research, but nothing specific was found. Active antileprotic treatment has been carried out, and the condition now appears to be quiescent or retrogressive. His general condition is good. The disease is not of the infective type, and it is probable that it will soon become completely arrested.

Special compensation was voted to this officer by Parliament. This is the second doctor who has contracted leprosy at a leper institution. The previous case was that of Sir George Turner, who retired from the post of medical officer of health for the Transvaal in 1903 on reaching pensionage. Part of his duties was to superintend the Pretoria Leper Institution, where he resided. On retirement he settled in Scotland, and two years later he informed the South African Government that he had developed leprosy. The disease was at first of the slow-developed type but later developed more rapidly, and became of the mixed (anæsthetic and nodular) type. He died in March 1915. Two other European leprosy officials and the son of a third have hitherto developed leprosy, and four Bantu employees at leprosy institutions have been admitted for this disease.

The Bangkok Leprosy Conference

The authorities of the Leonard Wood Memorial for the Eradication of Leprosy, acting in conjunction with the public health authorities of the Philippines and the Health Organization of the League of Nations, have arranged for a conference of leprologists to be held at Bangkok in January next, and have invited Dr. J. A. Mitchell, Secretary for Public Health for the Union of South Africa, to attend. On his outward voyage he will call at Delhi, where he will discuss several matters of mutual interest to the Union and Indian Governments, including precautions against the introduction of mall-pox into the Union by passengers from India. This is a subject of correspondence between the two Governments at present.

Governor-General's Farewell to the Medical Profession.

The Earl of Athlone was the guest of honour at the annual dinner of the Northern Transvaal Branch of the Medical Association of South Africa (B.M.A.), held on October 18th at Pollock's Hotel, Pretoria. In replying to the toast of his health he said he was convinced that some scheme had to be evolved to increase considerably the health services available to the very large native population in the Reserves and Locations of the Union. The question of a medical and nursing service among the native population had been very fully discussed at the medical congress which he had opened at Durban a few months previously, but it had eventually to be left over for further consideration. In spite of the very considerable difficulties he hoped that the problem would be tackled firmly, resolutely and expeditiously. He expressed his deep interest in the work of the Association. His previous experience in connexion with hospital administration in England, he said, had brought him into touch to some extent with the medical world, and had afforded him an opportunity of appreciating the enormous value of the Association. In bidding farewell to the Branch he extended his very sincere wishes for its future success and prosperity.

Ireland

Annual Meeting of the Ulster Branch.

THE annual meeting of the Ulster Branch of the British Medical Association was held on November 20th in the Medical Institute, College Square North, Belfast. Dr. J. C. Loughridge presided, and there were over seventy members present. He extended a hearty welcome to Dr. T. Henry, the Irish Medical Secretary, and the members of the Irish Committee present, this being the first occasion on which that committee had met in Belfast. He then introduced Mr. Howard Stevenson, the incoming president, who took the chair. Mr. Stevenson announced that a course of

post-graduate instruction was being arranged to be held early in the New Year at the Royal Victoria Hospital, and then proceeded to deliver the presidential address on oral cancer. In a comprehensive review of etiology and past and present methods of treatment, both of the initial growth and its secondaries, he was able to hold out considerable hope from radium treatment, combined, if necessary, with diathermy and x-ray irradiation. He stressed the enormous importance of employing treatment early, because many of the deplorable failures of past methods were due to the fact that the disease had advanced beyond real hope of cure when first seen. Dr. Killen proposed, and Dr. Armstrong seconded, a vote of thanks to the president for his valuable address. Mr. Stevenson, after expressing his thanks, introduced Dr. Hennessy, who reviewed the Medical Benefit Act, and emphasized the necessity for every member of the medical profession to join the British Medical Association in this way a united front could be presented when any question affecting its welfare arose. Dr. Leslie proposed, and Dr. David Gray seconded, a vote of thanks, and corroborated the need for organization of the profession. The president conveyed the vote of thanks to Dr. Hennessy, who replied.

Voluntary Aid for Hospitals

Since the institution of the Dublin Hospital Sunday Fund in 1874, the authorities have distributed £224,482. In the present year the contributions to the hospitals totalled £3,557—a decrease of about £1,500 compared with 1921. With the passing of the Sweepstakes Act for the relief of the hospitals, the situation has become serious for those institutions which have opposed participation in sweepstakes, since it is thought that the charity-giving public will feel tempted to withdraw their voluntary contributions. At a special general meeting of the authorities of the fund, held in July, a resolution was passed that any hospital promoting or taking part in the promotion of a sweepstake, in pursuance of the provisions of the Public Charitable Hospitals (Temporary Provisions) Act, 1930, shall cease to participate in the fund, and shall not thereafter be readmitted as a participating hospital, except by a resolution. Of the sixteen hospitals which have long benefited from the Hospital Sunday Fund, St. Patrick Dun's and the National Children's Hospital are excluded from further benefit having participated in the sweepstake organized in connexion with the recent race in Manchester. Four other hospitals—namely, the Royal City of Dublin, Meath, Coombe, and Cork Street Hospitals—have decided to take part in the next sweepstake, which is already being organized. The following ten hospitals will continue to rely on voluntary contributions: Stevens', Mercer's Drumcondra, Rotunda, Royal Victoria Eye and Ear, Convalescent Home, Adelaide, Monkstown, Orthopaedic, and the Rest for the Dying.

Grangegorman and Portrane Mental Hospitals

In his report of Portrane Mental Hospital Dr. J. O'C. Donelan, resident medical superintendent, gives some interesting facts regarding the history and working of the institution. At present there are 3,731 patients, 2,084 being housed in the parent institution at Grangegorman, and the remainder at Portrane. Commenting on the undue deprecation that has occurred to various parts of the building he mentions that although the Portrane institution was built less than thirty years ago the entire slating has had to be renewed at a cost of £20,000, the original slates, obtained from France during the period of the prolonged strike in Penrhyn quarries, having become soft and porous. The wooden buildings at Portrane are stated to provide excellent accommodation for 350 patients, all on the ground floor. They were originally intended to meet a temporary emergency during the building of the main institution, but during that period the number of patients increased so rapidly that it was found impossible to dispense with them. When the Portrane demesne was purchased for the erection of a branch mental hospital, the number of patients in residence at Grangegorman was under 1,500. Among the causes that have contributed to the increased number of patients are the transfer of insane patients from the workhouses of the district, the recognition by the public that the mentally afflicted should be treated in mental hospitals, and the fact that many offenders charged before the magistrates are now certified insane. Since 1894 accommodation has been found for 2,200 additional patients, or 1,000 more than the number contemplated when the permanent buildings at Portrane were designed. Although the main institution in Grangegorman has been considerably improved and extended during the last twenty years, it is still necessary to utilize a part of the old Grangegorman prison for the accommodation of patients. The report also refers to the progress that is being made towards the establishment of a tuberculosis-free dairy herd on the farm at Portrane.

England and Wales.

St. Dunstan's

Each year an attempt is made in the annual report of St. Dunstan's to indicate in the title some special side of the activities of this institution. Last year the title chosen was "Fifteen years after," and in the present year the fifteenth annual report carries the inscription "An help meet for him," because special reference is made to the part played by the wives of the blinded in making the most of physically darkened lives. The little community which is indicated in the title "St. Dunstan's" consists of 1,911 officers and men, and 5,101 wives and children. It is claimed that in it no necessity has remained unrelieved, no legitimate and attainable ambition on the part of a blinded soldier has been refused encouragement, no eligible case has been denied admission to benefit, no blinded soldier has died without receiving an old soldier's funeral, and no widow or fatherless child has been left helpless. Accounts are given of the ways in which the various activities involved in these claims are being conducted, and the report is illustrated with photographs of the many industries which are undertaken. The greater part of the training of the new men who are still coming to the institution each year is carried on at Brighton. These are mainly cases in which the blindness due to war service has only recently reached the stage where it renders the men eligible for the benefits of the institution. The Brighton establishment forms also an ideal convalescent home for those suffering from illness, or who have had operations. It also shelters many men who were so seriously injured in the war, in addition to their blindness, that their physical weaknesses (and too often their mental deterioration) make them permanent invalids.

Central Midwives Board

At the December meeting of the Central Midwives Board for England and Wales a letter from the Birmingham branch of the National Council of Women enclosed a resolution welcoming the interim report of the Departmental Committee on Maternal Mortality and Morbidity, "which while it gives a message of hope to the possibility of a general reduction of maternal mortality and morbidity, recommends (1) the better education of the medical student in obstetrics, (2) better supervision of pregnancy, (3) the improvement of medical practice, and (4) the co-ordination of maternity services. It therefore urges the medical and nursing professions and the public health authorities to do everything possible to improve and co-ordinate the health services of the nation to secure an improvement as soon as possible." It was agreed to send a reply assuring the branch that the Central Midwives Board was taking all steps in its power to assist in the bringing about of a reduction of maternal mortality and morbidity. Dr. J. J. Jervis was appointed to represent the Board at the Congress of the Royal Sanitary Institute at Glasgow next July, and Dr. R. A. Lyster to represent the Board at the Congress of the Royal Institute of Public Health at Frankfurt in May. The dates of the ordinary meetings of the Board for the year 1931 were fixed as follows: January 8th, February 5th, March 5th, April 1st, May 7th, June 4th, July 2nd, October 1st, November 5th, and December 3rd.

Cost of Tuberculosis Treatment.

A memorandum (122 D/T) has been issued by the Ministry of Health as in previous years at this season, indicating under different heads the weekly cost of treating patients with tuberculosis at various residential institutions in England and Wales during the year ending March 31st 1930. These figures have been tabulated as in former years and it appears that the total cost of each patient per week has increased often in consequence of additional expenditure having been found necessary for renewals and repairs of the equipment in the institution. In previous memoranda emphasis has been laid upon the importance of keeping the beds constantly occupied, and this year it is satisfactory to note that there is an appreciable improvement generally in this respect as compared with last year. In some cases however it is obvious that more attention requires to be devoted by local authorities to the necessity of keeping beds filled to the greatest possible extent. The recommendation is repeated that when some beds in an institution are not required for patients from the areas served every effort should be made to obtain patients from other areas.

Correspondence.

TREATMENT OF VARICOSE ULCERS.

SIR,—The method of treating varicose ulcers employed by Mr. Dickson Wright and described by him in the *Journal* of December 13th (p. 996) is based upon the principle of overcoming venous stagnation by means of artificial support in Mr. Wright's own words "Put the hydraulics right and the ulcer will take care of itself." The methods of many of the older writers were conducted upon the same principle and in the hand of these practitioners these methods were very successful. Why, then, it may be asked, have they failed to give satisfaction when used by others, so that the treatment of varicose ulcer has still remained generally ineffectual?

The answer may be found in a little volume *Diseases of the Skin*, by Thomas Hunt, J.R.C.S., published some sixty or more years ago; my own copy is the ninth edition, 1871. In a masterly chapter on ulcers of the leg Hunt states that the 'principle on which all practical men are agreed is that of giving constant and equable support to the whole surface of the limb from the toes to the knee.' He says that the plans of treatment proposed severally by Messrs. Whately, Barnton, Scott Spender and others were all founded on the simple principle of giving due artificial support to the limb by the application of plaster or bandages; and that the extraordinary success attending the practice of each one consisted mainly in their skill and adroitness in applying bandage or plaster so as to get equable pressure. 'Modern surgery therefore,' he maintains, 'is competent to the treatment of ulcerative disease of the leg. There is I believe no essential defect in it; no necessity for anything new. Why, then, is it so notoriously unsuccessful? Mainly because the application of a bandage is looked upon as an easy and simple operation, whereas I know few operations in surgery more difficult to perform or requiring more painstaking practice than the application of a bandage to the human leg in such a manner that every portion of the limb shall receive equal and abiding support.' Then 'at the risk of being tedious by minute,' he details his method of application of the bandage. This method might with advantage be taught to every house-surgeon and be carefully studied by every medical man who has to do with these cases, and I would like therefore to quote it in full.

Application of the Bandage.—Before applying the bandage it should be rolled up very tightly and evenly, otherwise it will slip on being applied. The wound being dressed, the patient should sit in a chair and place the heel on the corner of another chair, so as to give room to apply the bandage to the heel. The first turn or two should be taken round the foot at the little toe, taking care that every turn is even, so that one edge of the flannel does not cut while the other is lax. The next turn should be round the ankle, just as far from the heel as is required to lay the bandage even and tight; next round the foot again, nearer the heel than before; then round the point of the heel and over the instep; then under the foot and slantingly enclosing the hollow of the inner malleolus it should be brought round the leg and afterwards round the hollow of the outer malleolus; then round the point of the heel a second time and round the foot a fourth time; then round the leg and then carried spirally over the calf up to the knee, allowing the bandage to take a turn on itself just as often as it fails to lie even and flat without such a turn. Care should be taken that the bandage is rather tighter round the foot and instep than round the small of the leg and calf. The bandage should reach to the knee where it should be pinned not tied and the stocking should be pulled over it, no garter being allowed on any account. If the patient complains that the bandage cuts anywhere it should be taken off and reapplied with additional care. It is very often requisite to apply a compress of fewer cotton wadding to the hollow of the ankle to secure sufficient pressure there especially if that be the seat of the ulcer which often happens. In the method of applying the bandage recommended in books on surgery and even by Whately himself this part is left altogether unsupported and the pressure is applied to every part of the leg except where it is most wanted. It requires some practice to adjust this matter nicely without putting too many folds round the foot but it may be done and is worth the trouble much as without it we may fail.

A *flannel bandage* is essential—moderately fine Welsh flannel not too coarse, for then it is too rigid and rough for the tender skin, neither should it be very fine otherwise it will fall into folds or become loose. It should be from six to eight yards long and exactly two and a half inches wide. So long as there is any discharge from the ulcer it will be necessary to apply a clean bandage daily and soiled bandages must be washed in not very hot water to avoid shrinking. During the treatment the patient pursues his or her occupation. Many of Hunt's patients walked several miles to be dressed, and then walked back again.

The success of Hunt's method depends then mainly upon the care with which the details of the bandaging are carried out and no doubt the same may be said of the elastoplast bandage method. Drs. Twiston Davies and Drynan indeed hint at this when they say that the results have been poor when their technique has been attempted by those who have not actually seen the method demonstrated practically. I have myself used and taught Hunt's flannel bandage method for many years and on account of its simplicity and its efficacy as an ambulatory treatment have preferred it to strapping, Unna's paste, Martin's bandage, crepe or domett bandage or any other method of securing the same principle of continuous and uniform support.

Whether intravenous injection is an essential part of Mr. Wright's method is to me not quite clear, but I gather that it is not since he states that the 'advent of the injection treatment has not altered things very much.' The method of blocking the vein by intravenous injection was of course not known to Hunt, but it is interesting to note what were his views as to the value of other methods of obliterating the veins. It has been proposed, he says, "to relieve the venous pressure which originates these ulcers by cutting out the portion of the vein containing the diseased valves. This is uncertain in its results and by no means a safe operation. A better plan" and here he seems to anticipate intravenous injection "is to bind a small piece of nitrate of silver on the vein, but there is reason to believe that, as the varicose veins often disappear after the bandage has been worn for a few months, the valves recover and resume their proper office without any operation for their destruction."—I am, etc.,

London, W.1, Dec. 15th. H. C. ADAMSON.

CHOLERA EPIDEMIOLOGY.

SIR,—The obituary notice referring to Professor Haffkine which appeared over the signature of Sir William Simpson in your issue of November 8th rightly calls attention to the great debt the Empire owes to the memory of that savant not only in regard to life saving in the plague- and cholera-stricken populations of India but also in the British Army. I hope that the good work fulfilled by Haffkine need not be regarded as terminated by his decease.

In 1894 at the First Indian Medical Congress in a conjoint paper by Haffkine and Simpson the following statement was made. In different parts of Calcutta

and Howrah, and in examining cesspools connected with cowsheds in which cows had been ill, we found commas in the cows and in the cesspools The results of further investigation on this subject we hope to be able to communicate on a future occasion" In his annual report for that year, as health officer for Calcutta, Dr (now Sir William) Simpson stated that, owing to pressure of other work, it had not been possible to deal further with the matter I hold the possible connexion of cattle with cholera spread as of great importance, and I suggest that, as the originators of the idea were not in a position to complete the work, it is one well worthy of full investigation in India with the aid of the India Research Fund

Of recent years cholera research has been largely confined to the question of "carriers," agglutinability of vibrios, and the suitability of the environment of the human intestine for inducing virulence, yet in India cholera prevalence clearly coincides with meteorological conditions, whilst in large divisions of the country dietetic conditions do not differ materially with the seasons—unless it be in the composition of the water imbibed following meteorological influences As affecting the vitality of vibrios—which, as it happens, would accord with this aspect of the matter—various saline solutions have been experimentally utilized by Trenkmann[1] Dr Tombs and Captain Maitra, by laborious bacteriological examinations, have shown that in a typical Bengal tank cholera vibrios differed greatly with the cold weather, the hot weather, the occurrence of rain showers, the establishment of the monsoon, and breaks in the monsoon They found that the "chemical analysis of the water of ground tanks with high vibrionic content usually revealed a higher percentage of organic matter than in tanks not so heavily affected" They used the information so gained by modifying the media for cultivation Incidentally, therefore, they thus recognized the crucial fact that, granted the presence of vibrios, the qualitative composition of the water containing them is an important factor in their vitality I suggest that had they been able to add to their already heavy task the securing of chemical analysis of water side by side with their bacteriological work *throughout the period of seasonal changes* (when necessarily nitrification of organic matter in surface water and in subsoil water would undergo marked comparative changes) the long-disputed connexion between cholera epidemicity and meteorology would have been finally demonstrated Dr Tombs and Captain Maitra found that 35 per cent of the apparently healthy population they dealt with were 'carriers" Greig, in his original work, found six out of twenty-seven supposedly healthy persons

Such considerations bring into relief Pettenkofer's now little-respected theory In India, in the seventies, it was treated with scepticism Nevertheless, Cunningham and Lewis declared it was applicable to Calcutta, and, later, Kenneth Macleod maintained that it was operative in Bengal as a whole In 1882 I was placed by the Government of Madras on special duty to report on a severe epidemic which occurred in the city of Madras In my published report, after recounting facts on which I based my conclusion, I stated "There was a decided connexion between the maximum prevalence of cholera and fluctuations of the subsoil water, at its rise the influence was probably slight, at its fall it was intensified, and as it reached certain limits underwent diminution and cessation" By 1894 I had the advantage of dealing with conditions as found in the Madras Presidency (142,000 square miles) I collected data in a diagram,[3] since known as the "Madras cholera clock," which an able successor (Lieut.-Colonel A J H Russell, C B E), who has made a special study of the epidemicity of cholera, has stated "still keeps time"[4] Relying on these data, I stated at the First Indian Medical Congress (1894), in reference to subsoil water influence, as follows "So long therefore as *fluctuations* in the water level are proceeding, so long cholera is possessed of favourable opportunities for spread, but the moment its maximum or its minimum level is reached cholera ceases to be thus favoured" Obviously, the alternate rise and fall of subsoil water implies a varying extent of oxygenation of soil, with attendant grades of nitrification of organic matter as conveyed in the subsoil flow Later, I had the advantage of being kept informed by telegram of all first attacks of cholera throughout the area of the Presidency, and of their subsequent verified connexions until no longer traceable I formed the opinion that, granted favourable local conditions existed, notwithstanding the introduction of a recently infected case or "carrier," were due sanitary care exercised, no spread would occur but, allowing for possible laxity in reporting cases promptly, I never conquered my unproved suspicion that, in an area infected *during its chief monsoon*, irrespective of proved recent introduction, there occurred independently a wave of endemic origin Here accord might well be found, in the presence of favouring seasonal water composition, unrecognized chronic carriers, a normal degree of multiple contamination of water incident to Indian habits, and mass attacks of vibrios in the hitherto healthy, that exalted virulence which is decisive of an epidemic

But such sources of *cholera* spread *would* be almost negligible compared with the possibility of bovines being "carriers," as suggested by Haffkine and Simpson's unfortunately incomplete work The truth of such an estimate must be obvious to those having the slightest insight into the daily routine use, domestic and ceremonial, of the dung of the sacred cow by millions of Hindus Here it is necessary to remember that the period of vitality of the cholera microbe in earth cannot be neglected, and that in rural areas of India the buffalo, which is not held sacred, is encouraged to feed on human faeces by way of increasing the milk supply The finding of the Austrian Plague Commission as to dogs would show that at least one microbe pathogenic to man (plague) may pass through an animal's intestines and retain its virulence without untoward results to the bearer—I am, etc,

W G KING
Colonel I M S (ret)

Hendon, N W 4, Dec 9th

MERCUROCHROME IN OCULAR DISEASE

SIR,—I was very pleased to see the article you published on December 13th by Mr T R Chambers of Bristol, on the treatment of ocular disease with mercurochrome I first used it at the Western Ophthalmic Hospital in October, 1927, on a case of Parinaud's conjunctivitis, which had resisted all other treatment Mercurochrome drops cleared up the case completely in two weeks, and there has been no recurrence of the trouble I have also found the drops useful in the conjunctivitis which one finds in patients with a tuberculous history Mercurochrome is also very beneficial in clearing up chronic cases of dacryocystitis—I am, etc,

J COLT MARSHALL

London, W 1, Dec 17th

MINERS' NYSTAGMUS

SIR,—In certain quarters there is a feeling that the reports issued by the Medical Research Council are sometimes very unsatisfactory and by no means authoritative As an example, the two reports on the subject of miners' nystagmus, one published in 1922 and the other in 1923, seem to me to leave much to be desired In one of them there is a tolerably long paragraph on the diagnosis of the disease, and that paragraph makes no reference whatsoever to the very important cardiac symptoms, to the nyctalopia, to the hemeralopia, and to the pain in certain well-defined areas of the skull, which features appear to be the cause of the incapacity which the disease produces The movements of the eyes are often present in coal-pit workers without their producing any incapacity until the pits are lit with bright electric lights, when intolerable photophobia frequently ensues

Now as regards the investigation, it should be mentioned that one of the investigators, who believed the disease to be an eye disease, could not even take a visual acuteness, and did not manifest any great familiarity with the use of the ophthalmoscope Miners' nystagmus is, in certain cases, a fairly prevalent disease, and the reports issued by the Medical Research Council do not seem to have relieved the situation in the least Yet the present

[1] *Centralbl. f. Bakt* 1893 Abt 1 xiii No 10
[2] *Indian Medical Gazette* lxii No 2 February 1927 ibid February, 1925 p 56 and November 1926 p 537
[3] Reproduced in Sanitation Number, Tropical Diseases Bureau, July 15th 1919
[4] *Indian Journal of Medical Research*, 1928-29, xvi.

Minister of Mines appears to take them as being authoritative which I think is an untenable position

There is the further question of miners nystagmus being absent in other occupations where the lighting is extremely bad nor does it exist among the Kimos although their hovels are extremely badly lit The disease is rampant in certain districts and entirely absent in others If the light theory be adopted—as it seems to be by the Minister of Mines—it means that in certain areas the lights are chronically defective while in others they are always satisfactory That is how the matter stands—I am etc

Rhayader Dec 11th FREELAND FIRTH

AMIDOPYRIN IN MEASLES

SIR,—Having given my experience of twenty four cases treated by amidopyrin (*Journal* June 28th p 1198) I would like to point out that Dr Attlee's nine patients were at ages of from 12½ to 16 years but those of Drs Ronaldson and Collier were 9 and under Of their 150 cases 140 were of 5 years of age and under Their observations were on measles at ages at which it usually occurs in general practice Drugs act differently at different ages as is shown in the cases of morphine and atropine and the organism of a child of 5 is quite different from that of one at puberty These observations though differing totally are really not contradictory but seem to show that from 1 year up to 9 years amidopyrin has a definitely good action on measles but that over 12 it is not indicated Perhaps the age limit will be drawn closer by others who may try the drug—I am etc

London S.E.5 Dec 13th HOWARD B GRADSTONE

NOCTURNAL INCONTINENCE IN CHILDREN

SIR,—The recent correspondence on the subject of nocturnal enuresis in children shows that there is no specific remedy Enuresis is a symptom common to a number of causes which may be local or general one method of treatment will not therefore meet all complaint The supposed cause having been decided upon one of the recognized aids to treatment should then be brought in for relief

We have the choice of several method at our disposal and cannot afford to despise any of the time-honoured so-called 'cures" Drugs undoubtedly have their place Bromid and belladonna (the latter pushed in large doses) are used with successful results by some practitioners Bromide especially in a nervous child is of great benefit The highly strung child begins to sleep better the appetite returns and the world of fear becomes less terrifying, with the result that the wet bed presents a less formidable difficulty and begins to be less frequent Ergot in a child round about 5 years old is helpful iron and fresh open air are other aids for the anaemic child, better health being followed by greater control

If the incontinence is thought to be due to inability of the bladder to hold the normal quantity—and this is more common in the neglected child—abstention from fluids after 5 p m should be made a rule the child quite easily gets into the way of doing without fluid until the next day This is no hardship but it is necessary to get the willing co-operation of the child To awaken the child at 10 p m, and possibly, once again before the morning is of doubtful benefit it may do more harm than good to break his sleep and certainly with little ones this should not be practised Irradiation with ultra-violet rays, and also electricity, have cured some cases and this method is worth exploring Acid urine, without definite pyelitis is hardly ever a cause of chronic enuresis The "dry night" chart as mentioned in Dr T W Hill's letter of December 13th (p 1025), is undoubtedly a great help to many

Of surgical measures circumcision is of great value in selected cases Good results follow when the prepuce is tight and adherent and where secretion of smegma is in excess causing irritation and difficulty in cleaning Older boys with long and thickened foreskins derive much benefit from circumcision The psychological stimulus of going into hospital and undergoing an operation undoubtedly in some cases has the desired effect, the result of hospitalization for some other illness has had a curative effect in a number of cases in fact this has been noticed so often that it is well worth while to send a boy into hospital for a fortnight as an in-patient Results while in hospital are invariably good, but more often than not a lapse occurs on going home Psychologically this is of great use to the child for he finds that he can be dry The enucleation of unhealthy tonsils and adenoids has brought health to some Here again the process of healing is a complex one the fact of being in hospital helping to bring about a cure

Punishment acts as a deterrent to a cure and no threat to any child must be used Boards and uncomfortable beds have no place in dealing with the trouble which causes enuresis Such method only cause distress to the child, and cannot be too strongly condemned We must bring every means we know to the help of the child in his desire to overcome the habit, and the sympathetic aid of mother or nurse is a *sine qua non* Harshness or impatience at home may be the cause of months of disappointment to the child and the right home atmosphere is of the utmost importance

These remarks lead up to the most potent means at our disposal—namely the treatment of the mind the better the mind is understood, the more successful will be the results Mental factors are of great importance in the healing of physical weaknesses Once the child's confidence has been gained he must be disabused of fear or a sense of self-depreciation and he should be given a cheerful outlook on life It unhealthiness of the mind whatever this may be due to, is causing the bed-wetting it must be tuned to the reception of healthy and normal ideas It is not easy to know how soon the human being begins to have mental conflict, or how early he is open to bad mental suggestion he certainly understand kindness at a very early period The treatment of the mind is the most encouraging of the means at the disposal of the medical adviser in the cure of nocturnal enuresis—I am etc,

London E.1 Dec 15th A H MACDONALD

SIR,—I have read the recent communication in the *Journal* on this subject and desire to suggest that those who have such cases to deal with should try adrenaline or ephedrine

Both these drugs contract the trigone and relax the fundus of the bladder and it was on learning this fact that I first used adrenaline in nocturnal incontinence As adrenaline is destroyed in the stomach and hypodermic injections in these cases are not practical politics I give instructions that five minims or so of the 1 in 1 000 solution are to be dropped under the tongue and retained there as long as possible before swallowing Since ephedrine—which is not destroyed in the process of digestion—came into use I have given it with equal success in doses of half a grain for a child of 10 or 12 years of age The dose is given at bedtime, the usual precautions as to emptying the bladder before and two hours after going to sleep being adopted the results are immediate I have had quite a number of these cases in the past five years and only one failure (which was afterwards cured by enormous doses of belladonna) and I am led to consider that these drugs are almost "specific"

In this connexion it is interesting to note that one of your correspondents lately found that an asthma patient of his treated by adrenaline for the relief of his attacks suffered from retention of urine afterward—I am etc

Brackley Dec 13th. J E PARFITT D.M

THE WORK OF LABORATORIES

SIR,—Sir Walter Fletcher is really incorrigible I convict him of the grave offence of misquotation and reprove him very tenderly in proportion to his demerit He replies, not with apology or withdrawal but with a shoal of petulant irrelevancies, he repeats his offence in even more reprehensible form, and excuses himself as a humorist! In one sentence of his speech which I criticized Sir Walter jumbled together a number of statements made by me in Toronto Two of these gave my meaning not inaccurately others were garbled and corrupted I objected to the

latter, and completely disproved their claim to represent my views I am told in reply that I "must not run away from" the former Was there ever such obliquity of argument?

Let me first deal briefly with Sir Walter's irrelevancies He says that my address gave rise to "consternation" in Canada What has that to do with his defilement of it? Or the circles in which he moved, and of himself, at that moment I think in Canada, it may be true, to produce such an effect on him and those like-minded with him was indeed my hope and firm intention, and I rejoice greatly at his unsolicited testimony to my success Of other very different effects on all sides it would not be becoming for me to speak, but I receive overwhelming evidence of it from most responsible sources, even to the very day on which I write Would Sir Walter care to see it? In all directions, therefore, my desires appear to be fulfilled A further irrelevance deals with his criticism of my choice of time and place for such an address The plea in my address was for the return of truant physiology to human problems a cry for help from those most competent now *to give it to the clinicians* No more exquisitely appropriate place in all the world could have been chosen than the city in which the greatest of all recent discoveries had by this very method been made, and no more fitting time than that when the discoverer himself was present to receive honour What a faculty Sir Walter has for blunting the fine points of sensitive understanding Time, place, subject, were all perfectly attuned, the opportunity unique, my choice inspired

I cannot chase Sir Walter, an elusive quarry, into all his haunts of inaccuracy and misrepresentation, but some of them, at least, must be destroyed, lest he shelter therein again Sir Walter writes "Lord Moynihan quoted a rhetorical question in his address" ("Is scientific work by the physician or surgeon limited to the application in his art of scientific results worked out elsewhere in the laboratory and delivered to him for use?") "and pretended that it had been asked in serious doubt" The words of the annual report of the Medical Research Council which immediately follow the "rhetorical question" are "The mere fact that these questions can be seriously asked, etc ." Sir Walter is not only careless in handling my words, but quite forgetful of his own

I am newly accused of "disparagement of our physiologists and biochemists as such" Those by now familiar with the reckless inexactitude of Sir Walter's quotations will hardly need to be told that there is not one single word in my address to justify statements so utterly divergent from any opinion I have expressed I write "Physiologists are justly proud of the great conquests of knowledge which lie to their credit *English physiologists have pride of place* in many discoveries of recent years" What charming "disparagement" I speak of them as "among the ablest minds of our profession," as "highly competent scientific men", and there is much more in the same strain As to the charge that I "belittle the recent work of British laboratories," may I put myself to the pain, in all humility, of asking if any surgeon in this country has ever directly done as much as I towards the foundation of laboratories, and the support of the workers? I will confidently answer for myself that no surgeon could ever regard these matters as a more necessary or a more honourable part of his duty

Sir Walter seems unable to reconcile my warm appreciation of physiologists and their work with my lament that "the science of hominal physiology is more and more neglected" Does it not occur to him that it is my deep appreciation of the need of physiology to support and inspire clinical work that excites my protest? Cannot even he see that the chief purpose of my address was not to "belittle physiologists as such" but was an earnest, almost an anguished, appeal that their great scientific abilities might more often find application to human problems, in respect of which they were, and are (let me repeat it lest I am thought to be "running away"), too somnolent, too aloof from medicine, to our great loss and theirs? It was in this connexion that I made my comment upon the Medical Research Council, of which Sir Walter is secretary He is himself wholly unfamiliar with, and (if his views are represented in the annual report of the Council) a little disdainful of, the clinical activities of members of his own profession, a little too truculent over the supremacy of laboratory workers For example "It is important here to draw at once a clear distinction between the work of the physician engaged in practice and the work of a man engaged in the task of advancing knowledge," says his last report In my opening address at Guy's I read this sentence, and asked what their own physicians engaged in practice—Bright, Addison, Hodgkin, Wilks, Moxon, Pagge, Hale-White, Hurst, Ryle—had done to advance knowledge This note of estrangement from clinical affairs is really deplorable I pointed out that it is due to the fact that upon the Medical Research Council there has never (let me emphasize *never*) been adequate clinical representation I have now good reason to hope that my protestations may lead to changes in the near future, and I am therefore for the moment quite content But I deeply grieve that struggling in the net of my gentle criticism Sir Walter's flurry should bring him to the state of intellectual confusion which he so unhappily displays, and should permit him to use methods of controversy, misstatement, and irrelevancy, which are unworthy of him May I beg him to rid his mind of prejudice, and to read my address once again, not to "admire the eloquence and moving beauty" (for that tribute I am grateful) in it but, what is far more important, to appreciate the truth (for it is surely that) of its message? —I am, etc ,

London, W , Dec 15th MOYNIHAN

⁂ We have sent a proof of Lord Moynihan's letter to Sir Walter Fletcher, whose reply, printed below, brings this correspondence to an end —ED , *B M J*

SIR,—Lord Moynihan's address contained several mutually destructive propositions His way, as I said before, is to evade responsibility for what he said by quoting something else he said in an opposite sense But your readers now have ample material, if they have the patience, to form their own opinions of his modesty and his dialectical method —I am, etc ,

London, W , Dec 19th WALTER M FLETCHER

LOTTERIES AND SWEEPSTAKES AND HOSPITAL FINANCE

SIR,—This method of financing hospitals would be not only ethically unsound, but would at once cause a closure of the source of their present income—namely contributions from patients and the voluntary gifts of generous donors, both of whom would be deprived of the pleasure of expressing their gratitude and the enjoyment of helping good work Far better would it be to establish a sound contributory scheme for all classes than to encourage the gaming and acceptance of something for nothing, which is derogatory to the national character —I am, etc ,

Eastbourne Dec 15th A DEANE, M D

THE DISCOVERY OF TRICHINA SPIRALIS

SIR,—In your issue of October 11th is an interesting note on the discovery of *Trichina spiralis* The correction is timely, though the confusion is surely unnecessary when one notes that the case is rightly though briefly stated in the well-known English textbook, *The Animal Parasites of Man*, by Fantham, Stephens, and Theobald (1916) and in numerous other works Inadvertently, and apparently in the brevity of statement, your writer has made an unfortunate slip in the last sentence in discussing the life-history of this parasite, where he omits the name of Joseph Leidy of Philadelphia In 1846 Dr Leidy found an encysted worm in the hog He "could perceive no distinction between it and specimens of *Trichina spiralis* which he had met with in several human subjects"

In 1880 Nolan stated, in a sketch of Leidy, that "Leuckart afterwards acknowledged he was indebted to this communication for his success in tracing the development of *Trichina* in hog and man" In 1896 Virchow, in personal conversation, told of his correspondence with

study in 1849 and 1850 and stated that this suggested to him and to Leuckart the scheme of experimentation in the life-cycle of the parasite Leidy's demonstration was really the key to the solution of the problem The case is discussed in detail in my paper on "The founder of American parasitology Joseph Leidy" printed on the occasion of the sixty-centenary (*Journal of Parasitology*, September, 1923, 1-21).—I am, etc

ROBERTSON v MISKIN

MEDICAL MAN'S SLANDER SUIT AGAINST PARTNER.

In the King's Bench Division, before Mr Justice Horridge and a special jury an action for slander was brought by Dr Graham Robertson of Dartford against his partner Dr Leonard John Miskin The plaintiff alleged that defendant had stated that he (Dr Robertson) was addicted to drug taking and had stolen drugs which were their joint property

Sir Boyd Merriman K C and Mr E C Palmer appeared for the plaintiff and Sir Patrick Hastings, K C, and Mr J C Joseph for the defendant

Sir Boyd Merriman stated that the parties had been in partnership since 1911 but had always been antipathetic in character and outlook In February, 1929 the plaintiff had an acute attack of gastritis but the defendant suggested that he was shamming and reproached him for being out of the way at a busy time In July of that year Dr Robertson consulted a medical colleague who gave him a prescription but Dr Miskin made an unsympathetic remark and apparently by this time had persuaded himself that his partner's condition was due to the habit of excessive drug taking In August the plaintiff went to France for a holiday but Dr Miskin believed that he had remained in the purlieus of Dartford in order that he might come back into his house and obtain drugs to satisfy his craving The defendant told the lieutenant Dr Watson, that a large quantity of drugs was missing and that he suspected Dr Robertson of taking them He communicated the same suspicion to a regional medical officer who was making a routine inspection visit A few days later he tackled Dr Robertson him self on the subject saying that he did not believe that his illness was due to his heart but due to the taking of morphine and that seven eighths of the morphine contained in a bottle in the surgery had disappeared Dr Robertson who absolutely denied the insinuation set out to discover the real cause for the disappearance of the morphine and a nurse who was in the house was caught in the act of taking it She was shortly afterwards admitted to a Salvation Army home for drug addicts the matron of which recognized her as an occasional inmate during the previous seven years

Dr Miskin in evidence for the defence said that he had noticed the disappearance of many ounces of morphine from the dispensary between the end of August and the middle of October and connecting it with the plaintiff's bad state of health he came to the conclusion that the plaintiff was using it He mentioned his suspicions to the regional medical officer whose duty it was to see that the morphine was not being misused In so doing he was actuated by no feeling of ill will but merely by a desire to protect the interests of the partnership He spoke to the plaintiff on the subject because he was seriously alarmed about the missing drugs It was not until later that he heard that the nurse had taken the morphine Negotiations were at that time going forward to determine the partnership but these came to an abortive end in February of the present year the plaintiff having in the meantime raised his terms In saying what he did to the plaintiff and others he did not intend to convey the meaning that Dr Robertson was rendering himself unfit to continue practice as a doctor but he had believed that he was rendering himself less fit as a doctor by taking drugs and was endangering the partnership business

In reply to Sir Boyd Merriman Dr Miskin said that he did not now believe that Dr Robertson's illness was due to drug poisoning or that any of his previous illnesses were due to that cause He had some appreciation of what Dr Robertson must have felt when he realized that he had been suspected for a year of drug taking and he added that he felt regret for what he had done this was the first time he had expressed regret to Dr Robertson

Sir Patrick Hastings submitted that the words complained of were not actionable that they were not spoken of the plaintiff in his capacity as a doctor and his Lordship said that he would rule that all the occasions were privileged

Mr Justice Horridge in summing up said that his ruling that the occasions were privileged would protect Dr Miskin unless the jury thought that he had used the occasions in some improper way If he had acted honestly he had the greatest reason for investigating what his partner, Dr Robertson was doing, and a perfect right to make the statements he did to the other two doctors Before the jury could find that he was actuated by malice they must be satisfied either that he did not honestly believe what he said or that he used the occasion intending to injure Dr Robertson or from some other indirect motive, such as to assist him in getting the partnership dissolved

The special jury found that the words complained of were not spoken of Dr Robertson in his professional capacity that they did not impute to him any unfitness in his profession nor the criminal offence of stealing drugs and they also found that Dr Miskin was not actuated by malice

Judgement was entered with costs for Dr Miskin

Obituary

LIEUT-COLONEL N S SIMPSON, I M S,

Inspector-General of Prisons Bengal

LIEUT COLONEL N S SIMPSON Indian Medical Service Inspector General of Prisons in Bengal, was assassinated by Bengali anarchists in Calcutta on December 8th Three Bengalis in European dress entered Writers Buildings in Dalhousie Square, Calcutta, the headquarters of the Bengal Government and Secretariat and ran along the main corridor firing into each of the offices they passed Colonel Simpson was sitting in his chair in the first office, six or seven shots were fired at him one of which struck him over the heart killing him instantly The only other officer hit was Mr John Wood Nelson Legal Remembrancer, who was struck by a bullet in the thigh but was not dangerously wounded The three assassins were chased into an office where they turned their revolvers on themselves and when the police entered they found one man dead and the other two seriously wounded

Norman Skinner Simpson was born on January 1st, 1881 the eldest son of the late Charles Skinner Simpson He took the Scottish triple qualification in 1905 and entered the Indian Medical Service as lieutenant on September 1st 1906 becoming lieutenant-colonel after twenty years service After seven years on military duty he entered civil employ in 1913 and served for about a year on plague duty but reverted to military duty at the beginning of the war in August 1914 During the war he served successively in Egypt in 1915 in Gallipoli in 1915–16 in the Mahsud campaign on the North West Frontier of India in 1917, and again with the Egyptian Expeditionary Force in 1918 After the war he again took up civil duty in February 1921 entering the Indian Jail Department After serving for some time as superintendent of the Presidency Jail in Calcutta he officiated for six months as Inspector-General of Prisons Bengal in December 1925 and was appointed to that post in October 1929 In 1908 he married Edith Helen daughter of Major-General F R C Wilcox, Bengal Staff Corps, and is survived by her and one son

Lieut Colonel W C HAMILTON I M S (ret) writes Lieut Colonel Norman Skinner Simpson succeeded me as Inspector General of Prisons Bengal in October 1929, little more than a year ago Our work brought us into close association for several years and during the last six years of my service our relation were even more intimate, and when in Calcutta I saw him practically every day both officially and in ordinary social intercourse Simpson had a high standard of duty and never spared himself I am glad to say that our official relations were always very happy and I do not remember to have had any serious difference of opinion with him on matters of jail policy Our view on penal reform were identical He was a humane man and held enlightened and very progressive views on the treatment of prisoners When I was on leave in England in the summer of 1929 convalescing from a severe attack of enteric fever he took up the English

prison system and methods, and went through the course arranged by the Prison Commissioners for overseas prison officers He never lost his keenness for purely professional work, and kept himself well up to date in medical knowledge He did some good work investigating the incidence of hookworm among Bengal prisoners when he was superintendent of the Presidency Jail, Calcutta Simpson was an enthusiastic sportsman, and had a good eye for all ball games, he was one of the best amateur billiards players I have seen He had a judicial mind and wonderful tact, which made him an ideal jail officer He paid me a generous tribute on my work as Inspector-General of Prisons (which I greatly appreciated) in the annual report of the Bengal Jail Department for 1929, issued a few months ago It is sad to think that his work was cut short by such a tragic ending I have suffered a personal loss by Norman Simpson's death which cannot be replaced

---

With the death of Dr WILLIAM MCLEAN, county medical officer of health for Ross and Cromarty, the medical profession in the North of Scotland loses an outstanding personality, and many individuals their truest friend and mentor He graduated at Edinburgh in 1892, and for some years was in general practice with Dr Adam of Dingwall and later in Fortrose When the Countess of Seaforth opened her sanatorium at Maryburgh in 1908 he became its medical superintendent, and in 1920 he succeeded the late Dr Bruce as M O H for the county "H W" writes When any epidemics occurred Dr McLean seemed to combine the modern scientific certainty with an instinctive knowledge which guided him to a right course of action In 1923 a mysterious outbreak of food poisoning occurred at Loch Maree, and McLean was the first to recognize it as botulism The Department of Health trusted him as a sure guide to many problems of rural hygiene in the Highlands, and many official Orders were modified through his influence By the community in which he worked and the public bodies whom he served, he was regarded with unique and affectionate respect He leaves no written works behind him, although his research into Mesolithic remains alone would have made the reputation of another man It was a drawback to his seemingly inexhaustible range that his talent for expression seemed disinclined to leave anything in a permanent mould To some, whose minds did not move quickly, his public addresses appeared fantastic and full of picturesque exaggeration, but in any controversy he was always several moves ahead of his opponent, and seemed merely to be interpreting a deeper and hidden scheme of things At public meetings no one ever spoke more frankly and forcibly, yet made fewer enemies He had the gift of stating a proposition so brilliantly and in such a form that to oppose it seemed not only fruitless, but imbecile Yet his case was always so broad and free from prejudice that it commanded an instinctive assent Dr McLean was at his best as a talker, especially when describing human evolution In a strain of vivid and mordant expressions, with humour and without a trace of pedantry, he would describe the cosmic movements of the Gaels, the Iberians, and the Alpine men before the land bridges were sundered His eyes flashed then, and his charming smile left an unforgettable memory

---

Dr JOHN HARRY MAYSTON, who died at Clapton, E, on December 1st at the age of 45 received his medical education at Guy's Hospital, and obtained the diplomas M R C S, L R C P in 1907 He subsequently held the posts of house-surgeon at the Central London Ophthalmic Hospital and at the Bolingbroke Hospital During the war he held a commission in the R A M C, was seriously wounded, and eventually invalided out of the service He had been in failing health for the three years before his death Dr Mayston was a member of the City Division of the British Medical Association He married in 1911 Edith, daughter of Walter Morgan of Wrotham, Kent, who survives him

The following well-known foreign medical men have recently died Professor ACHILLE SCLAVO, director of the Institute of Hygiene of Siena University, Dr MARTIAL LANNELONGUE, formerly professor of clinical surgery at Bordeaux, Professor LUDWIG REHN, formerly director of the surgical clinic at Frankfurt University, aged 81, Professor ERNST THOMAYER, senior physician to the neurological department of St George's Hospital, Hamburg aged 62 Dr HUMMEL COOVER, formerly professor of ophthalmology at Colorado, aged 77, Dr L C LEHR, formerly professor of urology at Georgetown, aged 54, Dr WOODS HUTCHINSON, formerly clinical professor of medicine, New York Polyclinic, aged 68 of cerebral haemorrhage Dr KENKICHI ASAHI, professor of dermatology and syphilology at Kyushu University and president of the Japanese Dermatological Association, aged 57 Dr PIERRE GUIGES, professor of pharmacology at Beyrouth, and corresponding member of the Academie de Medecine aged 62, Dr SAMUEL LIVINGSTON LAMB clinical professor of medicine, Indiana University School of Medicine, aged 71, Dr CHARLES LUCIUS RICES, emeritus professor of nervous and mental diseases, University of Minnesota, aged 76, and Dr GILES CHRISTOPHER SAYRE professor of ophthalmology at the Vanderbilt University, and formerly editor of the *Ophthalmic Review*, aged 76

The Services

No 14 STATIONARY HOSPITAL

THE eleventh annual dinner of the No 14 Stationary Hospital was held at the Trocadero Restaurant London on December 12th, with Lieut Colonel J R Harper C B E in the chair The toast of The Hospital was proposed by the chairman, who expressed his pleasure at the steady continuance of these annual meetings, and welcomed back Colonel M Perry Dr H Letheby Tidy the organizer of the dinner gave an account of the doings of some who had been prevented from being present and the greater part of the evening was then devoted to reminiscences

---

DEATHS IN THE SERVICES

Lieut Colonel Thomas James Potter O B E R A M C (ret), died at Totnes, South Devon, on September 6th He was born at Queenstown, co Cork on September 15th, 1874 the son of the late Surgeon Robert Potter R N was educated at the Catholic University, Dublin, and the Royal College of Surgeons Medical School, and took the L R C P and S I in 1897 After filling the posts of senior resident surgeon and medical registrar at the Jervis Street Hospital, Dublin and house surgeon of the National Eye and Ear Infirmary Dublin and serving for nearly a year as a civil surgeon in the R A M C he entered the R A M C as lieutenant on January 27th, 1901 becoming major on January 27th, 1912, and retired on half pay on account of ill health, due to war nephritis, on September 23rd, 1922 being at the same time promoted to lieutenant colonel After serving in India and in the Aden Hinterland in 1908-10 he was employed in the pathological laboratory at Millbank under Sir William Leishman and Sir David Bruce From December, 1910 to August 1911, he was on special duty under the Colonial Office in Jamaica, investigating the so called "vomiting sickness" He was then employed as pathologist at the Citadel Hospital in Cairo, but, having come to England on leave in July 1914, was sent to France with the Expeditionary Forces, and commanded the 6th Field Ambulance in the Second Division in the advance to and retreat from Mons, and in the battles of the Marne and the Aisne at Ypres and in 1916 on the Somme He was subsequently with No 30 General Hospital at Barfleur, and, later, commandant of the military orthopaedic hospital at Blackrock co Dublin He was mentioned in dispatches in the *London Gazette* of January 4th, 1917, and received the 1914 Star with rosette the war medal, and the Victory medal, and also the O B E After retirement he lived at Totnes, where he took great interest in local first aid work and in the British Legion He leaves a widow

Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT]

On December 16th the National Health Insurance (Prolongation of Insurance) Money resolution was considered on report. Mr. Greenwood afterwards brought in the bill which was read the first time. On December 17th this bill passed through all stages.

Dame Louie McIlroy addressed the Parliamentary Medical Committee on December 16th, her subject being maternal mortality and its prevention. She advocated further education of medical students and of midwives in the prevention of the problem.

In the House of Lords on December 17th Lord Marley for Earl Russell presented the Pharmacy and Poisons Bill. This was read a first time without debate and has since been printed. It is a Government measure based on the recommendations of the Departmental Committee on the Poisons and Pharmacy Acts. Further modifications of the text have been under discussion with representatives of the pharmacist.

Before Parliament adjourned for the Christmas recess on December 19th the Royal Assent was signified to the National Health Insurance (Prolongation of Insurance) Act and to the Expiring Laws Continuance Act. A proposal to continue the Dye-stuffs Act for one year is included in the Expiring Laws Act.

Anti-Vivisection Bill

On December 16th Lieut.-Commander KENWORTHY asked leave to bring in a bill to prevent the application of public money to vivisection experiments. He explained that this was the third time he had introduced the bill. The British Medical Association had sent to him—and no doubt to other members—a document in reference to the bill asking for it to be opposed, and the ordinary reading of the document would make it appear that he wished to prevent those vivisection experiments. He might do so, but it was not intended to prevent them by this bill, and that would not be the result of the bill. There was a very wide objection to the money of the taxpayer and the ratepayer to the extent of £130 000 to £145 000 a year being devoted to subsidizing these experiments. If the experiments were to go on there were many wealthy institutions which could continue to support them, but it was unfair that the ordinary taxpayer or ratepayer who might object should be taxed against his will to subsidize the experiments. Many of these were unnecessary and a good deal harmless and useless, and as a practical means of economy there was nothing better than to save this money. There had been a tremendous increase in the number of these experiments, and that increase could not possibly be warranted by the results. In 1927 there took place 13 871 cutting operations with anæsthetics and 279 431 experiments without anæsthetics—a total of 293 302. In 1928 the figures had risen to 315 891 and in 1929 to 403 142—an increase of 87 250 in twelve months. That was unjustified and led to a great deal of unnecessary expenditure and undue extravagance. In 1929 513 animals, including cast army horses, were exterminated by poison gas experiments all paid for by the taxpayers' money against the conscience and desire of, he believed, a large majority of the people of this country.

Major CHURCH said that very few members would be reluctant to have a full discussion on this interesting and important subject, but as that was not possible in the circumstances he must, on behalf of the Medical Research Council, which body he had the honour to represent in the House, oppose the bill, not because he believed in giving unnecessary pain to animals. Very few members would like to see the slightest harm done to any of the smaller creatures. Very few of them would view with anything but misgiving any experiment clumsily carried out on any animal, whether it was for the purpose of curing it of a disease or in the course of experiment upon that animal with the object of saving human life. But they had to take into account other matters than sentimental considerations. They had to take into account the advance of knowledge and the uses to which animal experiments were put for the purpose not merely of saving human life, but of saving animal lives themselves. When he reminded Lieut.-Commander Kenworthy that we should probably have half the cattle of the Dominions destroyed if we were not able to use animals for the purpose of experiment, he hoped that he would consider seriously the position in which he would place this country or any country if he pursued this bill.

Lieut.-Commander KENWORTHY said that he did not wish to prevent these experiments, but only to prevent our money being spent on them. Major CHURCH replied that it would be extremely difficult to differentiate between money spent directly by the State in State research institutions, such as the National Institute for Medical Research at Hampstead and similar institutions, and that which was granted by the universities and other research bodies in the country carrying out experiments on animals. Lieut.-Commander Kenworthy had quoted the number of experiments carried out on animals in three consecutive years and gave apparently some alarming figures which mounted from 300 000 approximately in 1927 to over 403 000 in 1929. The hon. member should realize that the greater number of those experiments were experiments in which there was not the slightest suspicion of pain being inflicted on the animals, and in which there was no necessity for an anæsthetic. A large number of those experiments were carried out on mice, rats, guinea-pigs and animals of that kind, to test the various diets which were afterwards standardized for the cure of certain specific diseases among children—rickets, for example. A cure for rickets was established by experiments on animals. Every one of those experiments involving merely the feeding of animals on certain foods in a certain way had to be tabled as an experiment and done under licence by the Home Secretary. Under the Bill such experiments would necessarily be excluded. Many friends of his were engaged at present in a whole series of experiments on mice, rats, hedgehogs and other similar animals for the purpose of carrying out certain tests in regard to pituitary and other glandular extracts. Those experiments were of the simplest kind. They consisted of the injection by hypodermic syringe at certain times of certain substances. Every experiment of that kind—the tiniest injection that was made—had to count for the purpose of the bill as an experiment. The case against the bill had been stated quite clearly and specifically by the British Medical Association in a circular which he understood had been sent to every member. The case had been more fully considered and stated more specifically and even more clearly and pointedly by the State body itself, the Medical Research Council, in a memorandum which was issued for the information of members of Parliament in 1927. Since then there had been really remarkable results from experiments on animals. Members might feel that a good deal of pain was inflicted, but experiments of a serious nature were only allowed under regulations and only under the most stringent conditions were animals allowed to live after serious experiments had been carried out on them. In all other cases the animal were destroyed. The experiments were carried out under an anæsthetic. He thought that the House would acquit him of any desire to perpetuate a system that would lead to inhumanity.

On a division leave to bring in the bill was refused by 170 votes to 156. Dr. Addison, Dr. Forgan, Dr. Fremantle, Dr. Elliot, Mr. Hastings, Dr. Morgan, Dr. Morris-Jones, Dr. Salter, Dr. Drummond Shiels, Dr. Ethel Bentham and Dr. Williams voted against the bill.

Spahlinger's Serum.

On December 15th Dr. Addison, replying to Mr. Hurd, said that Captain Richard Buxton had presented him with a summary of the report on experiments with M. Spahlinger's vaccine which had been carried out on his farm in Norfolk. He had suggested to Captain Buxton in the interest of all concerned in the problem that he should arrange for a complete test to be made by and under the independent control of recognized authorities who were experienced in research in this disease. So far as the Ministry was concerned it was anxious that this vaccine should be properly tested. Dr. FREMANTLE: Is the right hon. gentleman in touch with the Medical Research Council and the Privy Council, which are the bodies responsible for these researches? Dr. Addison asked for notice of that question.

Gas Experiments at Porton.—On December 11th Mr. FREEMAN called the attention of Mr. Shaw to the allegation that the effect of many drugs and poisons such as prussic acid, belladonna on rabbits, opium on pigeon, lemon juice on cat, and strychnine on monkey was different from their effects on human beings. Mr. SHAW answered that these allegations afforded no reason for disregarding the connexion between the effect of various gases on animals and their effect on human beings. The experience in the war established it. Asked by Mr. Freeman whether he did not think such experiments were useless, Mr. Shaw said that he had taken the best professional advice and was satisfied that the experiment as carried on at Porton were necessary in the interests of research.

X-ray Examination for Tuberculosis.—Mr. GREENWOOD on December 4th told Mr. Somerville Hastings that the number of x-ray examinations made in 1929 for every 100 persons examined in tuberculous dispensaries of England and Wales slightly over twenty-five. He had no information on how many of these examinations resulted in the confirmation of a diagnosis

Definite arrangements for x ray examination had been made by 122 out of 140 tuberculosis authorities in England and Wales, and by all the metropolitan borough councils Other tuberculosis authorities had from time to time provided x ray examinations for particular cases

Suicides in England and Wales—On December 9th Mr GREENWOOD replying to Mr Kinley, gave a return of suicides in England and Wales in the past ten years This showed that in 1920 52 males and 49 females under 20, 556 males and 338 females between 20 and 40, 1,415 males and 513 females between 40 and 65, and 404 males and 98 females of 65 and over committed suicide, the total being 2,427 males and 998 females In 1925 the total had risen to 2,852 males and 1,232 females, in 1926 it was 3,099 males and 1,350 females, and in 1927 3,458 males and 1 449 females In 1929 the figures were 3,480 males and 1,504 females

Radium—On December 16th Mr GREENWOOD, replying to Commander Bellairs, said that he was not aware that the last Government had given any undertaking to refer the question of radium supplies and prices to the League of Nations He was, however, informed that proposals for investigation of these matters were made at the last session of the Health Committee of the League of Nations and would be further considered at the next meeting of that committee

Universities and Colleges.

UNIVERSITY OF OXFORD

AT a congregation held on December 17th the following medical degrees were conferred

D M—R S Creed E B Strauss
B M—F R Crookes M A Hatt F M Trofusis, Q St L Myles, J M Lees, R S Harrison E H Rink, N C Parfit H R J Donald, H C Harley, Anne D M Adams

UNIVERSITY OF LONDON

THE following have been recognized as teachers of the University in the subjects indicated St Bartholomew's Hospital Medical School, Dr L P Garrod (pathology), Dr C F Harris (diseases of children), Mr H G Bedford Russell (oto rhino laryngology), Middlesex Hospital Medical School, Mr D H Patey and Mr E W Riches (surgery), Charing Cross Hospital Medical School, Mr W H McMullen (ophthalmology), London (Royal Free Hospital) School of Medicine for Women, Miss Mildred Wardle (oto rhino laryngology)

The Senate has noted with pleasure that the governing body of King's College Hospital Medical School had decided to admit ten women annually to the medical school

The regulations for the academic Diploma in Public Health (Red Book, 1930-31, p 469) have been amended by the addition after the words A mark of distinction will be placed against the names of those candidates who show exceptional merit" of the following 'in the whole examination, whether taken at the same time or in two parts'

Mr H L Eason, C B, M S, has been elected chairman of the Library Committee

A Rogers Prize of £100 will be offered for award in 1931 The subject is 'Filterable viruses as a cause of disease in man" Essays or dissertations must be received by the Vice Chancellor by April 30th, 1931 Copies of the regulations and any further information can be obtained from the Academic Registrar

The title of Emeritus Professor of Fine Art in the University has been conferred on Mr Henry Tonks F R C S, on his retirement from the Slade Chair of Fine Art at University College

The degree of D Sc in biochemistry has been conferred on Mr G F Marrian, and that of D Sc in physiology on Mr Philip Eggleton, both internal students of University College

Sir George Newman, K C B, has, on the recommendation of the Board of Management of the London School of Hygiene and Tropical Medicine, been appointed Heath Clark Lecturer for the year 1931

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

The next series of eight lectures and demonstrations on tropical hygiene, which are intended for men and women outside the medical profession proceeding to the Tropics, will be given by Lieut Col G E F Stammers from January 14th to 23rd, at 2 p m A second series of lectures will be given from March 18th to 27th at 5 o'clock These courses of instruction, in addition to providing simple rules for guidance in regard to preparation for life in the Tropics and personal hygiene, will also embrace a short account of some of the more common diseases, with advice in regard to measures of protection against such diseases and some guidance in simple methods of self treatment Syllabuses and full particulars can be obtained on application to the secretary, London School of Hygiene and Tropical Medicine Keppel Street, Gower Street, W C 1

UNIVERSITY OF MANCHESTER

THE following candidates have been approved at the examination indicated

FINAL M B CH B—A N Birkett B R Bramwell S T Cowan, C G Eastwood J R P Edkins Dorothy A Geller E W Hardman, L Jones D Ockman H I O Loughlin B P Robinson G H C Walmsley *Part I Forensic Medicine and Hygiene and Preventive Medicine* C B Ainscow G H M Franklin, J K Hadfield, J F E Johnson E D Portman

Medical News.

AT a meeting of the Illuminating Engineering Society in the board room at 28, Grosvenor Gardens, S W, on Monday, January 12th, at 6 30 p m, a discussion will be held on recent developments in gas lighting

THE Mental After Care Association, founded in 1879, appeals for funds to maintain and extend its work on behalf of poor patients who have recovered from mental disease Its main object is to aid the convalescence of such patients from all parts of the country on their discharge from public mental hospitals by ensuring for them a period of rest and change under skilled and sympathetic supervision For this purpose a large number of cottage homes have been established in the London area and in the country where patients are encouraged to adjust themselves to normal conditions On their recovery they are assisted by grants in kind or money, and efforts are made to find them suitable employment The association also facilitates the early treatment of mental disease by arranging for the residence of patients in the neighbourhood of hospitals and clinics The average number of patients assisted during the past year was 194 every month Apart from contributions from authorities and persons concerned, the funds available are wholly derived from voluntary subscriptions and donations While administrative expenses have doubled within the last ten years, the benefits administered have increased sixfold The association is non sectarian, and is the only charity organization in the country devoting its entire resources to work of this kind Communications should be addressed to the secretary, Church *House, Dean's Yard, Westminster, S W*

THE second National Congress organized by the Italian League for the Campaign against Cancer will be held on January 4th and 5th, 1931, in the Anatomical Institute of Bologna University, under the presidency of Professor Giacinto Viola The following subjects, among others, will be discussed modern views on the etiology of tumours (Professor P Rondoni), cancer and tuberculosis (Professor E Centanni), the problem of constitution and cancer (Dr P Benedetti), and diagnostic and therapeutic centres for

malignant growths (Professor P Gallenga) An international exhibition of the literature of malignant growths will be held during the congress The subscription of 20 lire should be sent by those intending to join the congress to the general secretary Professor V Dalla Volta, R Clinica Medica, Policlinico S Orsola, Bologna

THE first Congress of Latin American Ophthalmology will be held at Santiago (Chili) in 1931, under the presidency of Professor Charlin

A MEDITERRANEAN cruise will be organized by the *Bruxelles Medical* next year, leaving Marseilles on March 28th and returning thither on April 23rd The places to be visited include Tripoli Alexandria, Jaffa Beirut Rhodes, Stamboul (Constantinople) the Piraeus (for Athens), Corfu and Naples Special charges are available for medical practitioners and their families and also for laymen who are recommended by their family doctor Optional excursions will be organized in every port The minimum charge for medical practitioners is £37 18s first class, and £22 18s second class The steamboat which will be used is the *Champollion* of the Messageries Maritimes, it contains state cabins and also cabins for one two, three and four persons Further particulars may be obtained from the Section des Voyages of the *Bruxelles Medical*, 29, Boulevard Adolphe Max, Brussels

THE Minister of Health with the approval of the Prime Minister has appointed Sir E J Strohmenger to be Deputy Secretary to the Ministry of Health in succession to Mr J R Forber and Mr S H G Hughes to be Principal Assistant Secretary for Finance and Accountant General of the Ministry

THE ninth scientific report on the investigations of the Imperial Cancer Research Fund, which has just been published by Taylor and Francis price 20s, contains twelve original contributions and four reprints of articles which appeared in the *British Journal of Experimental Pathology* and the *Biochemical Journal* The eighth scientific report was published in 1923

WE have received a copy of the December number of *Antiquity* which completes the publication of the fourth volume It is insufficiently known that this quarterly—which is a distinguished product of the printer's art—is not devoted exclusively to the interests of the student of archaeology Thus the present number includes a very interesting account of the lion and the unicorn by Mr Cyril G Bunt, who traces their traditional rivalry through fifty five centuries of symbolic art His contention, which would dispose of the widespread notion that the legend is in any sense peculiarly British, is that the device is a religious symbol, representing the triumph of summer over spring The potency of the unicorn's horn is familiar to readers of Renaissance medicine Another article in this issue reviews Professor Herzfeld's recent discoveries in Persia

THE centenary of the birth of General Antoine François Davila, who died in 1884 the founder of the Bucarest faculty of medicine and principal medical officer of the Rumanian army, has recently been celebrated at Bucarest

ACCORDING to Surgeon General H S Cumming of the United States Public Health Service, 470 cases of tularaemia with 17 deaths have hitherto been notified in the United States The nine north eastern States are the only ones in which no cases have so far been recorded

THE high incidence and mortality of measles in Egypt during the last four years are shown by the fact that during this period the incidence has ranged from 3 995 cases in 1927 to 22 365 cases in 1929 and the case mortality from 41 8 per cent in 1926 to 45 8 per cent in 1928

THE French Government has accepted an offer of the Rockefeller Foundation to establish a centre for the study of undulant fever at Montpellier

A MEMORIAL has recently been unveiled at Marienbad to Professor Samuel Ritter von Basch the father of sphygmomanometry on the occasion of the twenty fifth anniversary of his death

DR ALFONS JAKOB professor of psychiatry at Hamburg has been made a corresponding member of the National Academy of Rio de Janeiro and Dr Franz Groedel professor of roentgenology at Berlin a corresponding member of the medico chirurgical society of Bologna

GEHEIMRAT LEXER of Munich Alfred Guttich (professor of oto-rhino laryngology at Cologne) and Dr Siebeel (director of the medical policlinic at Bonn) have been appointed deans of the medical faculties

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to *The EDITOR British Medical Journal British Medical Association House Tavistock Square, W C.1*

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated Correspondents who wish notice to be taken of their communications should authenticate them with their names not necessarily for publication

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager British Medical Association House Tavistock Square W C 1 on receipt of proofs

All communications with reference to ADVERTISEMENTS as well as orders for copies of the *Journal* should be addressed to the Financial Secretary and Business Manager

QUERIES AND ANSWERS

Climate of Cairo

"T D R" writes I should like to know whether the climate of Cairo is suitable for a breast fed baby of 5 months and in what months of the year it is necessary to take the baby home because of the hot weather

Leucoplakia?

DR W E CODY (Twickenham) writes I should be grateful for the opinions of your readers on the following case The patient an artist aged 35 has suffered from psoriasis for many years In the last six months he has had several white patches each about 1/8 in diameter scattered over his tongue These patches are not raised above the mucous membrane but feel less soft than the healthy parts of the tongue There are also spots looking like aphthae seen in children on the buccal mucous membrane opposite the second molar teeth No history or stigmata of syphilis The patient looks and feels quite well, and is physically sound

Amenorrhoea in a Girl

DR N CARPP (Schweizer Reneke Transvaal) writes In the *Journal* of October 18th (p 670) "M E I" asks for advice as to the persistent amenorrhoea in a patient of his Let him prescribe an alkaline powder Pot cit sod bicarb āā 5ss in 2 ounces of water or milk thrice daily—that is 180 grains per diem To be used daily for a month The periods will most probably reappear long before the month has passed For further information let him read the article on "Acidosis in amenorrhoea" by Osman and Close in the *Practitioner* of April 1930

LETTERS, NOTES, ETC

Relation of Diabetes and Cancer

DR J N MCINTOSH (Jamaica) calls attention to the excessive formation of lactic acid in the growth of cancer cells a process which appears to be checked by pancreatic acid He states that diabetes is more prevalent than cancer among the black and coloured population of Jamaica and suggests that such a comparison is worth working out as regards the various world races He writes I am more than ever convinced that there is a close relation between a faulty carbohydrate metabolism and malignant growths and that the hormones (especially that of the islets of Langerhans) closely linked up with the reaction of the autonomic nervous system determine whether the local pathological process is to be one of diabetes or malignant neoplasm It seems that if the tissues first become thoroughly "bathed" in fermentative products from an auto intoxication (so-called "antibodies") it is utterly impossible for a malignant growth to appear even although there may be a hereditary tendency and the only disease present will be diabetes On the other hand if the pancreatic "antocold" through its chalones causes a "mild" depression on the tissues then the pathological process present may be malignancy the outstanding feature associated with a glycosuria.

Determination of Sex

DR N MCCONNELL BOYCE (Romford) writes In the *Journal* of November 13th, 1926 (p 918), I suggested that sex determination was a question of pre menstrual or post menstrual conceptions, the former tending to produce males and the latter females From letters received and further notes in the *Journal* it appeared that observers agreed that the time of insemination with relation to the menstrual period did determine sex, but while one group believed that conceptions before menstruation produced males, the other group were of the opinion that pre menstrual insemination resulted in females I agreed with the first group, and had great success I [illegible] obtain children of the desired sex, but in one [illegible] boy rule did not apply This woman was [illegible] the pre-menstrual girl rule I attended two of her three confine ments In each she had taken care that the time of insemination was in accordance with her rule, and in each she had a baby of the sex desired by her The truth appears to be that there is a sex-determining factor in the relationship between the time of conception and the menstrual date, but for each individual that relationship has to be worked out It may well be impossible to prearrange or predetermine the sex of the first child, but from the facts of this first birth it is a simple matter to calculate the sex-determining rule for the particular mother For example, a woman bore a full term male child on October 10th, counting back 281 days from that date, the probable date of conception is reached—namely, January 3rd The mother dates the last period from December 26th, 1929 to January 1st, conception, therefore, was post-menstrual The baby was a boy, and so the mother follows the post menstrual boy rule Giving this mother advice with regard to pre menstrual conception in order to obtain a girl, if desired, can do no harm This is the only means at one's disposal to probe the truth or otherwise of the theory The calculation from the date of birth may show that conception was midway between two periods, or rather was about ten days after the last period, and presumably about the same number of days before the period that failed to appear In this case nothing with regard to the individual's sex determining equation can be calculated, but conception at such a time is supposed to be rare I should appreciate hearing of specific instances which support the theory

Pond Snails in the Spread of Disease

DR F G CAWSTON (Durban) writes Although schistosomes capable of attacking man have not been recorded in Europe north of Portugal, allied parasites which depend on the water snail for a completion of their life cycle are common, in the summer of 1926 I found cercarine plentiful in pools at Frensham in Surrey and near Farnham and Bromley in Kent, while they have also been reported from other centres Though serving as one of nature's scavengers, snails in a stagnant pool become a source of danger to man when they are infested with trematode parasitic worms such as *Fasciola* and *Schistosoma* On becoming acquainted with bilharzia disease in Natal a colonist immedi ately recalled the experience of a boy with whom he had collected the eggs of waterfowl at the village of Aveley in 1880, and who contracted haematuria, which Dr *de Brent* attributed to his wading in the stagnant pools of the Mardyke tributary of the Thames, close to Purfleet in Essex Whether *Schistosoma* might have accounted for this condition or not, the presence of neglected pools on private property invites a danger from snail borne disease

NSPCC

SINCE the National Society for the Prevention of Cruelty to Children was founded forty six years ago it has dealt with over a million c[illegible] [illegible]ne of about 4 million children In this pe[illegible] [illegible]stablished over two hundred branches [illegible] Ireland, and has organized an extensive [illegible] and supervision Some idea of the vigilant protection it affords to the community may be obtained from the annual report of the society for the year ended March 31st, 1930 which reveals that the number of children on whose behalf the society intervened was 351 every working day, and that the total number exceeded the figure of the previous year by 6 000—a circumstance which is attributed mainly to successful propaganda Although the society is inclined to accept the suggestion that the standard of case reported is tending to become higher, it is disquieting to learn that cases of brutality increased by 294 during the year under review, and that the number of such cases—namely, 3,440—is as high as it was thirty years ago More reassuring is the decrease in the number of prosecutions, which are undertaken by the society only when all other methods of correction have failed The proportion of these cases (1 16 per cent) is the lowest recorded There is also evidence that an increasing number of parents are voluntarily seeking the advice of the society in matters affecting the welfare of their children The chief causes of neglect reported during the year were ignorance, indifference, laziness, drunkenness and gambling Slum conditions were found to be a recurrent evil, in 5 633 cases the families con cerned lived in single rooms, representing 13 per cent of the cases investigated in the course of the year In commenting on the amelioration of housing conditions the society points out that while the clearing of slum buildings and the rehousing of their occupants continues without interruption in our large cities, there is also need for reconditioning property unfit for habitation in rural areas, where schemes of this kind have received less attention Satisfaction is expressed that the society's Canal Boats Bill has been introduced into Parliament to give children living on these boats an opportunity of ele mentary education Another aspect of child welfare which has shown steady and progressive development in recent years has been the assistance the society provides in securing medical aid for sick children During the year 946 children successfully underwent operations in various hospitals in the country through the agency of the society's staff of inspectors These include eleven women, who are responsible for sick and ailing children in several of the large provincial towns More than a thousand children are reported to have recovered from minor complaints. In his annual report for the year Dr L D Saunders, medical officer to the society, refers to some of the difficulties in arranging for satisfactory medical treatment, owing partly to the limited accommodation of hospitals and institutions, and partly to the lack of proper care in nursing children in their own homes He insists that it is most undesirable that children recovering from encephalitis should remain at home without supervision The report contains a detailed statement of the London medical branch of the society

"The Royal Jennerian Society"

"D S M" asks for information about the Royal Jennerian Society He has acquired an honorary testimonial, dated September 29th, 1835, electing John Dove, Esq , as an honorary member

*** The Royal Jennerian Society for the Extermination of the Small Pox was started under Royal patronage at a meeting held in London on January 19th, 1803, at which it was resolved to call the society the "Royal Jennerian Institution" Dr John Walker was appointed resident inoculator The society's office was in Salisbury Square, Fleet Street The committee, after a time, disapproved of Dr Walker's proceedings, and he resigned Dr John Baron, in his *Life of Edward Jenner, M D* (London, 1838), says It lingered on for some time, but on the establish ment of the London Vaccine Institution in 1808, its finances being exhausted, its operations would appear to have ceased entirely An attempt was made in 1813 to revive this society, and the chairman of a general meeting held for that purpose, Dr Bradley, applied to Dr Jenner requesting his acceptance of the office of president He, in an answer dated Cheltenham, September 3rd, 1813, declined this proposal It is desirable that this fact should be remembered, inasmuch as it proves that Dr Jenner's name ought to be entirely disconnected from the proceedings of what is still unaccountably termed the 'Royal Jennerian Society'" Nevertheless, it appears that there is in the library of the United States Surgeon General at Washington a report of the Board of Managers of the Royal Jennerian and London Vaccine Institution to the governors for the year 1851, and that that association was formed by the union of the Royal Jennerian Society for the Extermination of the Small Pox and the London Vaccine Institution We have found no record of the existence of the society after 1851

A Home for Invalid Ladies

DR L N HERSKITH BIGGS writes I want to bring to the notice of your many readers a home for invalid ladies of limited means, who earn their own living, situated at San Remo, Italy, a spot which is considered to have the best all round climate on the Riviera The "Villa Emily" was built by an English artist for his own use, and is a commodious house in a large sheltered garden All the rooms face south, and wide verandahs run almost the entire length of the two floors The object of the institution, which was started over fifty years ago and deserves to be better known, is to provide a comfortable home for ladies in ill health who need a winter in a warm sunny climate to fit them once again for their duties It is under the patronage of Princess Beatrice, is run by an English committee, and is in the charge of an experienced trained matron with trained nurses under her Each lady has to pay £2 a week, which sum is quite inadequate to cover expenses, and the annual deficit is made up by generous friends Medical attendance and nursing are given free The home has central heating, and has been extensively renovated Information and forms may be had from Miss Janet Kay Shuttleworth care of Messrs Coutts and Co, 440, Strand, London, W C 2, from June 15th to October 1st, and Villa Luna, San Remo, Italy, from October 1st to June 15th

The New Mercurial Diuretics

Correction

IN our report of Dr Warren Crowe's reference to the use of salyrgan in Ménière's disease, made at the meeting of the Section of Therapeutics of the Royal Society of Medicine (December 20th, p 1047), the name *Mygind* was incorrectly given as Meakin

Vacancies

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 38, 39, 41, and 42 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 40 and 41

A short summary of vacant posts notified in the advertisement columns appears in the *Supplément* at page *272*

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

560 Clinical Features of Arterial Hypertension

H Vergeer (*Journ de Méd de Bordeaux*, October 10th 1930 p 725) discusses the symptomatology and pathology of high blood pressure in the light of the clinical findings in four patients Three of these latter were under the age of 45, and all showed hemiplegic manifestations in the course of their illness It is pointed out that the transient symptoms described by Dieulafoy as early signs of Bright's disease—for example, vertigo, headache, numbness of the fingers, and claudication—cannot be due solely to the hypertension which is permanent, but are more likely referable to local fluctuations in the peripheral circulation Such signs as these and transient paralyses were found principally in patients showing no great rise of blood pressure—that is, in patients as yet unadapted to the new pressure level Vergeer classifies the dangers of hypertension as follows cerebral haemorrhage ischaemic cerebral softening and renal insufficiency Rupture in minute cerebral vessels in a patient whose vascular system is little diseased may lead to hemiplegia from which recovery ensues, whereas rupture of sclerosed arteries into the capsule is almost always fatal Vergeer agrees with the view of Josue and Vaquez, that hypertension is the primary manifestation in most cases *arterio-sclerosis being a secondary phenomenon* Patients suffering from long standing hypertension and showing no evidence of haemorrhage or encephalopathy, ultimately acquire renal insufficiency they may die of uraemia or the myocardium may fail first giving rise to the common form of cardio renal failure It is remarked that the prognosis in high blood pressure is worse in the earlier decades and better after the age of 50 but the ultimate fates of the latter group of patients are the same Vergeer has no confidence in any specific drug for hypertension, he finds that hydrotherapy is only of passing benefit He recommends use of sedative drugs such as valerian and gardenal, and he advises the restriction of salt and nitrogenous foods in the diet

561 Active Immunization against Diphtheria.

According to G Moreels (*Per Belge Sci Med*, July–August 1930 p 710) a study of the statistics of the diphtheria department at the civil hospital at Ghent shows that during the period 1905–14 the mortality was 17 5 per cent from 1915–20 11.2 per cent, and from 1921–29 8 per cent Although there had been a progressive fall in the mortality the last figure which had shown no tendency to fall, is much too high and active *immunization on a large scale* appears to be indicated According to the author's observations 41 per cent of children, including those of school age are susceptible to diphtheria The percentage of those immune to diphtheria is lowest between the ages of 2 and 3 years it rapidly increases as the age diminishes and also with advance in age so as to reach about 60 per cent at the age of 7 years and during the rest of life Although anatoxin causes a general reaction less frequently than Henseval's vaccine which produced a local or general reaction in 100 per cent in 1928, it gave rise to severe local reactions in 80 per cent, and in 1930 in 55 per cent, half of which were severe These reactions as other observers had found were chiefly observed in adolescents and adults and were rare or slight in young children As regards the duration of immunity Moreels found that the children he had immunized with anatoxin in 1928 were still Schick negative in 1930, while 80 per cent of those inoculated with Henseval's vaccine in 1923 were immune in 1928 The 20 per cent who were susceptible were immunized the same year with anatoxin, and their Schick reaction in 1930 was still negative

562. Acute and Chronic Yellow Atrophy of the Liver

H Berg-Strand (*Nordisk Medicinsk Tidsskrift*, November 1st 1930 p 639) gives an account of an epidemic of yellow atrophy of the liver in 1927 in Sweden During the latter part of the war this disease began to increase in frequency but it was not till 1927 that the highest peak was reached In the period 1914–23 necropsies on only 25 such cases were performed in Stockholm and as many as 19 of these belonged to the five year period 1919–23 In 1927 necropsies were performed on 42 cases in Stockholm and simultaneously 97 similar cases were observed in other parts of Sweden The Stockholm cases showed two peaks one culminating in the summer the other in the autumn—a phenomenon very suggestive of an infectious disease Simultaneously with this increase in the frequency of acute yellow atrophy of the liver there has been an increase in the *frequency of catarrhal jaundice* in Stockholm and Gothenberg and for that matter, in the world at large With regard to the old observation that syphilis and pregnancy are the most important predisposing causes of acute yellow atrophy of the liver, the author notes that in none of his 97 cases did he find any sure sign of syphilis not one of the 72 women in this series was pregnant or in the puerperium On the other hand there was a history in many cases of some gastro intestinal disease or rheumatic affection in three instances the disease was ushered in by articular rheumatism Ascites was observed in about 20 per cent being most common among the comparatively chronic cases With regard to the chronicity of the disease, the author has observed several cases in which it lasted three to four years, and in one case the disease lasted ten years Jaundice was not an invariable sign, in some cases the clinical picture was that of cirrhosis of the liver and it was no until the necropsy that the true nature of the disease was discovered In addition to pointing out the many features common to catarrhal jaundice and acute and chronic atrophy of the liver the author notes that an attack of the first does not apparently confer immunity as regards the other two for in some of his cases there was a history of jaundice in childhood

563. Primary Mumps Meningitis.

G Esquief and L Protteaux (*Bull et Mem Soc Méd Hop de Paris* October 27th 1930 p 1507) refer to the recent paper on this subject by Weissenbach and G and M Basch (see *Epitome*, April 5th, 1930 para 318) and record a personal case in a soldier, aged 26 who during an epidemic of mumps in his garrison suddenly developed symptoms of meningitis The cerebro-spinal fluid showed an enormous lymphocytosis and slight increase of albumin The parotid swellings first on the left and then on the right side did not appear until the fourth day Recovery was rapid and uneventful

Surgery

564. Sepsis following Wounds of the Hand.

M L Mason and S L Koch (*Surg, Gynecol and Obstet* November, 1930 p 591) studied the routes of extension of *infection from the dorsum of the hand and report their* experience of thirteen cases suffering from human bite infections in this region Three factors appear to influence *the clinical and pathological picture such infections are* often prolonged and difficult to eradicate because the infection is introduced deeply through a comparatively small opening because of the anatomy of the involved structures, and because of the relatively low resistance of fascia tendon and bone to the mixed infections caused by organisms from the mouth With the hand doubled into a fist the tooth punctures the skin and extensor tendons while they are tightly stretched over the metacarpo-phalangeal joint usually the right second and third it may even penetrate the joint With the extension of the fingers the line of entrance is sealed off by the skin and gliding tendon Three spaces are infected thus—namely the dorsal subcutaneous the joint and *the dorsal subtendinous space between the tendon and* the capsule extension is determined by the anatomical arrangement of the tissues From injection experiments the course of the spread of the process as borne out by clinical experience, is described The resulting incapacity may be prolonged and except in very mild infections in which the organisms have not been introduced below the fascial sheets of the hand this has frequently to be reckoned in weeks and months rather than days *The most important* factors in treatment are the careful cleansing of the wound with soap and water without a tempting closure cutting away damaged tissue, and either the immediate application of warm wet sterile dressings or the instillation of Carrel Dakin treatment A *knowledge of the sites to which in*fection may spread is important in order that early and adequate drainage may be adopted to prevent bone joint and tendon involvement with resulting extensive impairment of function In order of frequency such sites are (1) the subcutaneous space of the dorsum of the hand (2) the subfascial space of the dorsum of the proximal phalanx (3) the subaponeurotic spaces directly over the metacarpals and proximal phalanges (4) the metacarpo-phalangeal joint and (5) the fascial spaces of the palm and flexor tendon sheath

565 **Congenital Torticollis**

D S MIDDLETON (*Brit Journ of Surg*, October, 1930, p 188) surveys 90 cases of torticollis and sterno mastoid tumour treated during the last few years The various theories of the etiology of these conditions are discussed, the ischaemic theory being described as the most modern and accurate It recognizes that the muscular fibrosis seen in torticollis is a similar process to that occurring in Volkmann's ischaemic contracture of the flexor muscles of the forearm The author differs from the belief that Volkmann's contracture results from arterial deprivation of the flexor muscles, and shows that such fibrosis in muscle can only result from venous obstruction, which probably takes place during labour in cases of sterno mastoid tumour It has been found that there is a definite relation between a sterno mastoid tumour and torticollis, it is stated that all cases of "congenital" torticollis result from fibrosis in the sterno mastoid muscle, consequent upon the development and absorption of the so called "sterno mastoid tumour" of infancy This tumour appears most commonly about ten days after birth, and remains more or less stationary for two or three months, it is then gradually absorbed and disappears at the end of four to six months after birth In some cases a slight torticollis may develop, but this may be only transient and of the nature of an acute torticollis In other cases a true torticollis may develop at about the age of 4 months, coinciding with the absorption of the tumour In 36 cases of torticollis 25 gave a definite history of a sterno mastoid tumour in infancy which underwent absorption and was followed later by the development of torticollis Out of 83 cases in which the history of the labour was known only 14 were normal, 46 were difficult or prolonged, 15 were breech presentations, and 8 were "crossbirths" It is considered that the temporary venous obstruction induced during labour becomes permanent owing to patchy intravascular clotting in the obstructed venous tree An exostosis was frequently found to occur at the clavicular attachment of the sterno mastoid muscle in cases of fibrosis affecting the clavicular head The facial asymmetry and plagiocephaly associated with torticollis is dependent upon the prolongation of the cervical curve into the base of the skull, and is described as a scoliosis capitis

563 **Biliary Fistulae following Cholecystectomy**

T H LAHEY (*Ann of Surg*, October, 1930, p 649) records the result of further operations performed for the transplantation of complete external biliary fistulae since 1923, when the author's first experiences with this procedure were published Ten cases are now reported, in six the patients are well and free from symptoms, one requires further operation since the complete external fistula returned, one was a partial failure as the patient suffers from frequent attacks of biliary obstruction, and two died following the operation It has been found that the fistulous tract may be cored out of the abdominal wall but should not be dissected free from the under surface of the liver It is therefore necessary to mobilize the stomach, duodenum, or jejunum so that it can be brought up to the anterior surface of the liver, the entire fistulous tract can then be pushed into the intestinal canal, the wall of which is sutured about it, and the stomach or bowel is sutured to the capsule of the liver In four of the cases under review spontaneous internal biliary fistulae had occurred, the duodenum or stomach attaching itself to the hepatic duct above a stricture, and establishing a small and inadequate spontaneous fistulous canal between the two In each of these cases the spontaneous fistulae were detached, and complete external biliary fistulae were established The fistula should be transplanted into the stomach whenever possible since it tolerates the introduction of bile satisfactorily, should leakage occur a gastric fistula is less dangerous than a duodenal or jejunal fistula

567 **Acute Peritonitis**

H PIRIE (*Med Journ and Record*, October 1st, 1930, p 328) calls attention to the value of caecostomy and enterostomy in acute peritonitis, he urges their performance earlier and more frequently to save the life of patients overcome by the toxaemia of obstruction In a bad case of appendicitis in which the peritonitis is well localized a caecostomy should be performed by inserting a tube into the caecum through the base of the appendix In cases with generalized peritonitis the performance of a caecostomy and an enterostomy has reduced the mortality of such cases more than 50 per cent The operation can be done under local anaesthesia even in desperate cases, with a remarkably immediate relief, in addition to acting as a drain the enterostomy can also serve the purpose of giving saline and glucose solutions to prevent the patient being dehydrated Through an incision to the left of the rectus sheath just above the level of the umbilicus a healthy loop of jejunum is clamped, and a purse string suture in the gut is pulled up and around a No 16 catheter inserted through a small incision A needle is carried through the catheter and a thread is tied to prevent slipping After removing the clamp a second purse string suture is placed above the first and tied round the tube Directly after the operation 500 c cm of 10 per cent glucose should be given by hypodermoclysis and 100 c cm every hour, with rectal enemata of glucose and soda every four hours, and about five ounces of 25 per cent glucose introduced through the enterostomy tube every hour

583 **Symmetrical Gangrene in Scarlet Fever**

G FREDERIKS (*Jahrb f Kinderheilk*, November, 1930, p 270) has collected eight cases from the literature, including those reported by Southey (*Journal*, 1883, vol I, 856) and Davies (ibid, 1891, I, 458) and records the following personal case A girl, aged 4 years, eight days after the onset of a mild attack of scarlet fever developed symmetrical areas of cutaneous gangrene on the upper arms, elbows, thighs, and legs The necrosis of the skin was the only complication present The blood picture contraindicated a septic infection, and the contents of the gangrenous lesions were sterile There was no reason to regard the skin as hypersensitive to scarlet fever toxin, since the Dick test was already negative on the twelfth day of disease A considerable portion of the lesions were absorbed and only superficial areas of necrosis resulted, complete recovery ensued

Therapeutics.

569 **Treatment of Whooping-cough**

E RADU and S ACKERMAN (*Journ de Radiol et d'Electrol*, October, 1930, p 559) comment on the frequent failure in whooping cough of such well known remedies as atropine, morphine, sodium benzoate, ozone, ethyl iodide, and quinoline The accidental discovery that radioscopic examinations were followed by marked improvement in two cases of this disease led them to try radiotherapy in all cases of whooping cough Two series of irradiations at seven to eight days' interval were administered The whole thorax was irradiated, the face, neck, and abdomen being protected, and the rays being centred on the middle of the sternum On the same or the following day the dorsal region was similarly treated, the rays being centred on the fifth or sixth dorsal vertebra The authors found that after the first application the paroxysms of cough became more frequent and intense, and the condition was apparently worse On the following day improvement was noted, and complete cure was established after the second series of radiations It is pointed out by the authors that the paroxysms of coughing are characteristic, and appear in the second period of the disease They may be serious and cause epistaxis, cerebral and meningeal haemorrhages, hernias, and broncho pneumonia Most medical treatment hitherto has been directed to controlling these paroxysms, but with little success, though Leopold and others have employed ultra violet rays with benefit The present authors have also tried these rays, but the results were much less satisfactory than when they used x rays, the exposures being made in the third and fourth weeks of the illness after all other therapeutic measures had failed The radiations act probably on the nervous system

570 **Therapeutics of Olive Oil**

WHILE advocating the administration of olive oil by the mouth in certain affections, CHIRAY (*Presse Med*, November 1st, 1930, p 1481) emphasizes the importance of employing an absolutely pure preparation The oil is emulsified in the intestine by the bile and pancreatic juice, a small quantity after saponification is split up into fatty acids and glycerin The undigested part of the oil is passed in the stools, either in a pure state or as fatty acid concretions, which are often mistaken for biliary calculi The use of olive oil has been gradually limited to the following diseases hepato biliary affections, gastro duodenal disorders and a few other conditions, including diabetes, pulmonary tuberculosis, and lead colic Various theories as to the action of this oil are reviewed, and it is shown that it possesses two properties—that of exciting the biliary secretion and of stimulating the flow of bile, it has no dissolving action on calculi In lithiasis olive oil is given in the painful crises of the disease to aid in the expulsion of calculi, it is also used in the troubles following cholecystectomy In these cases the dosage is one to two soupspoonfuls of the oil, either pure or mixed with a few drops of lemon juice which stimulates opening of the pylorus, thus lessening the time of the gastric retention of the oil This dose should be administered fasting, half an hour before breakfast, for ten days, with monthly intervals This method should not be used for the expulsion of calculi when the patients are very fatigued, infected, or suffering from marked hepatic deficiency, immediate operation is then

indicated After cholecystectomy olive oil is useful in the recurrences of hepatic colic and in the icteric syndromes which often remain as sequels In non lithiasic cholecystitis the same amount of oil is given hot in order to encourage vesicular contraction Olive oil with a little lecithin, such as the yoll of eggs is of remarkable benefit in cholecystatony, a condition characterized by vesicular distension independent of extrinsic obstruction and by a loss of tone and contractility of the cholecystic muscular tunic In hyperchlorhydria with or without ulceration this treatment is of great value One to two teaspoonfuls of the oil should be administered half an hour before the three or four daily meals this should be continued for two to three weeks and be often repeated at regular intervals In diabetic and tuberculous cases olive oil is useful if a digestive tolerance for fats and hepatic integrity be present In lead colic a glass of oil causes a cessation of the pains and a copious stool, with definite cure in three to five days

571 Pituitrin Snuff in Diabetes Insipidus.

K L Reksten (*Tidsskrift f d Norske Laegefor* October 15th, 1930 p 1125) was led to use pituitrin snuffed up the nose in cases of diabetes insipidus by the perusal of a paper by Adlersberger and Porges who had achieved striking successes in three cases They found that dry powdered extract of pituitrin given by the mouth was inert their successes were achieved only when they induced their patients to employ as snuff a dried powder obtained from the posterior lobe of the pituitary body and containing 2,000 Voegtlin units per gram Reksten describes two cases of patients thus treated the procedure proved to be remarkably effective provided that potent preparations were used Two different Norwegian preparations one of which contained 1 790 Voegtlin units in each gram were remarkably uniform and reliable in their action each patient used up 1 gram in the course of two to three weeks The first patient was a married women aged 48 the specific gravity of her urine was 1004 and she passed 8 to 10 litres in the twenty four hours After taking pituitrin as snuff only twice the excretion of urine fell on the same day to 3 5 litres She continued this treatment snuffing from one to four times a day with the same prompt success The second patient was an unmarried woman aged 27, who as long as she was suffering from a cold in the head obtained little benefit from the snuff When the cold began to pass off the snuffing became more effective and the excretion of urine fell from 13 to 2 litres She found snuffing two or three a day sufficient to keep the excretion of urine within normal limits On discontinuing this treatment for twenty four hours she found that her thirst and polyuria returned promptly so she resumed treatment at once During the two and a half months Reksten has treated these two patients he has observed no ill effects, nor has he had to increase his dosage

Laryngology and Otology

572. Mastoiditis from Contusion

T D Onofrio (*Arch Ital di Otol Rinol e Laringol*, July, 1930 p 332) who records two examples states that while cases of traumatic mastoiditis are not uncommon both in war and in peace mastoiditis from contusion without fracture or suppurative otitis media is very rare His first patient was a man aged 60 who as the result of a fall on the occipito-mastoid region developed a haematoma, which became absorbed in a fortnight eighteen days after the injury he began to suffer from severe pain in the mastoid region with pyrexia and a discharge from the ear No pus was found beneath the periosteum, nor any infiltration of the soft tissues but the mastoid was full of pus Recovery ensued in four months The second case was that of a man aged 47 who developed osteo periostitis of the mastoid without involvement of the middle ear as the result of sleeping in a train with his head resting on a seat, thus causing compression and contusing of the mastoid An operation was performed and recovery was complete in about two months

573. Middle ear Infection

J Lippi (*New York State Journ of Med* October 1st 1930 p 1146) dealing with the common forms of otitis media, states that the distinction between catarrhal and suppurative inflammation can be determined by taking into account the duration of the illness and the appearance of the drum He defines as indications for myringotomy an inflamed drum associated with severe pain which is not relieved by palliative measures or with high fever not otherwise accounted for or with marked ma toid tenderness Bulging of the drum is of secondary importance relatively and of itself does not necessarily call for incision since in the absence of pus such cases often recover Popper gives a brief outline of an ordinary case, indicating the treatment suitable at the various stages He calls attention to a sign of mastoid involvement which he has not found to be generally known—namely a doughy sensation on incision of the drum followed by the escape of very little pus A round perforation with smooth edges is suggestive of chronic otitis he recommends for such cases insufflations of iodine powder (Sulzberger) which he finds much more effective than the commonly used powders

574 The Blood in the Anginas

J J Shea (*Arch of Otolaryngol* September 1930 p 366) draws attention to the fact that a throat infection may be the initial or terminal manifestation of haematopoietic disease The changes produced in the blood are (1) polymorphonuclear leucocytosis, as seen in follicular tonsillitis (2) mononuclear leucocytosis, as in infective mononucleosis (3) leucopenia agranulocytic angina and (4) leucocytosis with relative increase in the large lymphocytes as seen in generalized Vincent s infection Shea points out that there are two varieties of agranulocytic angina, one that ends fatally and is usually seen in middle aged women, and a second which is a complex and is sometimes seen in arsenical poisoning In true agranulocytic angina various organisms have been recovered from the throat, but the exact etiology is uncertain The portal of entry is the initial sore throat though other mucous membranes may later become involved There is paralysis of the haematopoietic system and the extent of the throat lesion depends on the amount of lymphoid tissue remaining There is cervical adenitis but no other glandular enlargement In generalized Vincent s infection the lymphocyte count may rise up to 90 per cent of the total white cells This condition is usually fatal Acute infective mononucleosis is a relatively benign condition, and starts as an angina with the usual malaise and headache The cervical glands and the spleen are enlarged The lesion in the throat ranges from slight ulceration to extensive disease Although the presence of Vincent s organisms in smears from the throat is common examination of blood films by the oxidase process demonstrates the increase of large mononuclear leucocytes and differentiates this relatively benign condition from the very serious generalized Vincent s infection The author describes six illustrative cases and concludes with a plea for the study of the blood by expert haematologists in all cases of angina

Obstetrics and Gynaecology

575 Diagnosis of Tubal Pregnancy

L Stern and K Stern Dreifuss (*Med Welt* November 8th 1930 p 1621) remark that tubal pregnancies very often give rise to a mistaken diagnosis not only by the general practitioner but also by the gynaecologist The condition may be mistaken for acute cardiac failure appendicitis perforative peritonitis or an ovarian tumour, but most frequently it is diagnosed as an abortion and curetting is performed with fatal results In spite of the undoubted increase in tubal pregnancies in recent years the subject has received little attention as compared with appendicitis Within the last two and a half years, however the authors have had to operate on five cases of tubal pregnancy and only two of appendicitis Moreover, spontaneous recovery from appendicitis is frequent, whereas tubal pregnancy left to itself, is almost always fatal Haemorrhage after a period of amenorrhoea indicates a disturbance of pregnancy but whereas intrauterine abortion is commonest in the third month or later interruption of tubal pregnancy almost always occurs in the first four weeks after cessation of the periods The haemorrhage is accompanied by more severe pain than is the case in menstruation, and this pain sometimes radiates to the sacrum The general condition is at first good in the absence of a sudden haemorrhage into the abdominal cavity The temperature is usually somewhat raised On abdominal palpation there is distinct tenderness which is most marked on the side of the affected tube On vaginal examination there is a livid discoloration of the mucous membrane, especially of the cervix and the uterus is of normal size The administration of ergot or quinine is now indicated, since if the case is one of intrauterine abortion the uterine contractions will expel the decidua which can be recognized by the naked eye If no decidual fragments are found expectant treatment must be adopted The pain and haemorrhage may cease for from one to three days but then soon return and symptoms of collapse develop On vaginal examination a tender swelling is found on the side of the affected tube It gradually increases in size while the uterus remains unchanged The diagnosis of tubal pregnancy is then established

576. **Pregnancy and Epilepsy**

H BACHMANN (*Zentralbl f Gynak*, October 18th, 1930, p 2636) describes two cases in which pre existing epilepsy became much worse during pregnancy, with mental deterioration and status epilepticus respectively In both cases rapid improvement followed operative emptying of the uterus, combined for prophylactic reasons with tubal sterilization It has been stated that epilepsy is unaffected by pregnancy in about one third of cases, in the remainder, in equal proportions it becomes considerably worse or considerably better There is no evidence that pregnancy can either cause or cure epilepsy That the influence of the one condition on the other is probably due to hormones from the ovum appears probable from the fact that some patients have fits when carrying male but not female foetuses, and from the therapeutic results achieved by the induction of abortion Of the progeny of epileptics, it is said that only 20 to 25 per cent are healthy 35 per cent die young, 20 per cent are mentally defective, and 7 per cent are paretic or deformed Artificial termination of pregnancy in epileptics is held to be justified when the disease first appears during pregnancy, when it becomes worse during pregnancy, or by the presence of status epilepticus or severe mental symptoms, sterilization should be performed at the same time

577 **Primary Carcinoma of the Fallopian Tubes**

W W HOLLAND (*Surg, Gynecol and Obstet*, November, 1930, p 683) thinks that carcinoma of the Fallopian tubes is not so rare as formerly believed, the number of cases seems to be gradually increasing He doubts whether the etiological significance attributed by many writers to inflammatory changes in the tubes is warranted A correct diagnosis is possible only after macroscopical and microscopical examination, from which it appears that papillary alveolar and alveolar types are advanced stages of primary papillary malignancy A review of the records of the Mayo Clinic during the course of eight years brought to light only nine cases of primary carcinoma of the Fallopian tubes in a series of approximately 10,000 completely removed tubes In seven, one tube only was concerned, and two were bilateral, so that eleven primary carcinomata were actually found, an incidence of 0 11 per cent Carcinomatous growths were found in eighty one tubes, seventy of which were regarded as secondary in origin either by contiguity or metastasis The records of the Johns Hopkins Hospital showed an incidence of primary carcinoma in 0 04 per cent only, being found in five out of 12,000 tubes These statistics rather support the view that inflammation plays a less significant part in the development of the condition than has been thought

Pathology.

578 **Pathology of Bright's Disease**

IN a comprehensive paper D D VAN SLYKE *et al* (*Medicine*, September, 1930, p 257) record detailed observations of 67 patients with Bright's disease, who were followed up for periods ranging from a few weeks to several years The gross and microscopical findings in 17 of the cases are described These observations support the views of Volhard and Fahr and of Addis that the three types of this disease differ essentially in their genesis and pathology the haemorrhagic or glomerular, marked primarily by glomerular inflammation with haematuria and usually diminished renal function, the sclerotic, marked chiefly by changes in the small renal arteries, with hypertension as the first sign and diminished renal function only terminally, the degenerative disease or diseases, called nephrosis, characterized by degenerative renal changes, without hypertension and with haematuria Contrary to the general belief (except that of Addis), it was noted that gradual decrease of urea excreting ability frequently develops during nephrosis, and the disease may end in uraemia, the glomerula then being involved in the degenerative changes The renal pathological changes occurring during the disease could be deduced, this also is the view of the three authorities previously mentioned Diagnoses were chiefly made by noting the renal urea excreting power (measured by the blood urea clearance), the haematuria blood pressure, plasma protein content, proteinuria, and oedema In acute haemorrhagic nephritis the prognosis depended on the plasma albumin content, most cases in which this fell markedly became chronic Renal function (measured by the blood urea clearance) may fall to 10 per cent of the normal with apparently complete recovery The majority of the cases showed a decided fall during the first two months, but in those of improvement or recovery a rise began within four months after the acute onset The presence or absence of this rise was the most definite single prognostic sign Some cases of haemorrhagic nephritis, after the initial acute stage, were indistinguishable for a period from nephrosis In a few months, however, they either improved or recovered, which is rare in nephrosis, or became chronic Non cardiac oedema approximately paralleled the fall in plasma albumin content, except during the first weeks of the acute haemorrhagic type During this period oedema was reportedly noted, even when the proteins remained normal The oedema however, was moderate and temporary unless plasma albumin deficit developed In all stages of nephrosis this deficit and oedema were concurrent In arterio sclerotic disease plasma proteins were never markedly reduced, and only cardiac oedema was present The blood urea clearance proved to be the most clearly related to final renal failure If the renal function fell to below 5 per cent of the normal, uraemia, usually fatal, ensued Occasional acute cases can recover if the functional depression does not last too long, and rare terminal ones in which the fall is partly due to factors such as desiccation, other than destruction of the renal tissue The variations within each of the three types of Bright's disease were found to be great

579 **The Blood Lactic Acid Content after Muscular Contraction**

THE chemical changes connected with muscular contraction have been studied mainly in cold blooded animals M GRACE EGGLETON and C L EVANS (*Journ of Physiol*, October 31st, 1930, p 269) believe that the investigation of these changes in warm blooded animals is of value Such study must necessarily be conducted by somewhat indirect methods, among these is the estimation of the lactic acid in the blood as an index of its concentration in the tissues, including active or recovering muscles A series of experiments on dogs and cats are here recorded It was found that while the average lactic acid content of superficial venous blood closely parallels that of arterial blood, individual samples show variations The lactic acid content of tissues in general is somewhat less than that of the blood plasma, both at rest and during recovery from exercise, this difference is less readily observable in muscle, and up to about 10 per cent could be accounted for by the higher water content of the plasma The lactic acid content of muscles, severely exercised for a short period, does not equilibrate with that of the blood and other tissues until at least ten minutes after the end of the exercises In the equilibrium then reached the muscle lactate content is lower than the arterial blood lactate figure The lactic acid content of the venous blood returning from muscles which have been contracting remains higher than that of the arterial blood throughout recovery, while that from unexercised muscles is lower The lungs play no part in the removal of lactic acid during recovery Since the blood returning from the liver contains less lactic acid than arterial blood after recovery, the liver removes lactic acid from the blood In eviscerated animals the rate of removal was reduced to about one third, it is concluded, therefore, that the liver is not solely responsible for lactic acid removal The lactic acid content of the blood in resting eviscerated animals does not rise during the four hours following evisceration A few points on glycogen resynthesis in muscles during recovery from exercise are appended

580 **Neutralization and Excretion of Avertin**

W STARK (*Schmerz Narkose Anaesthesie*, October, 1930, p 247) states that according to statistics published so far the death risk in avertin anaesthesia is at least as great as in chloroform, untoward effects such as cyanosis, collapse, and the temporary suspension of respiration are relatively common Opinions vary as to clinical contraindications to avertin anaesthesia, cachectic states, liver and kidney diseases, and thyroid disorders, having all been mentioned Since avertin is apparently neutralized in the body and excreted in combination with glycuronic acid, it was thought that the risk in some of these cases might be due to a shortage of glycogen in the body The author therefore undertook a series of experiments on rabbits to determine the effects of starvation and of hypo and hyper thyroidism on the length of anaesthesia produced by avertin, and on the rate of its excretion as judged by the glycuronic output It was found that starvation enhanced the effect of avertin, it prolonged the anaesthesia, and delayed the excretion of the drug Thyroidectomy (performed four weeks before the experiments) had a similar effect, the duration of the anaesthesia being markedly increased The administration of thyroxin before the avertin was given produced uncertain results, there being a lack of correspondence between the length of sleep and the rate of excretion If severe hyperthyroidism was induced the risk of avertin anaesthesia was greatly increased, and many of the animals died during or shortly after the experiment, even though only a comparatively small dose of avertin had been administered.

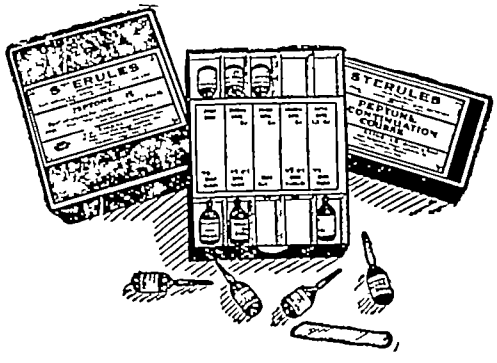
Overnight sterilisation of dentures

A Special NEW *Catadyn Model*

THE illustration you see here shows a new type of Catadyn Steriliser in the form of a Container for Dental Plates etc It is made in best white glazed Carlton ware with the Catadyn sterilising elements in the bottom below a perforated plate The Container is filled with water each night and the dentures placed inside As soon as the water comes into contact with the Catadyn sterilising elements the Catalytic Dynamic action takes place Dental plates are sterilised completely overnight



Size 3½in × 3in *Contents* 200 c c

The British Catadyn Company desire to secure the investigation of this remarkable invention by the medical profession A very interesting booklet will be sent on request, describing some of the applications now available The price of the dental steriliser as illustrated is 6/6, postage extra

Steriliser for CATADYN *Dental Plates*

INDIAN MEDICAL SERVICE

Recruitment of European Officers.

Applications are invited from medical men for permanent commissions in H.M.'s Indian Medical Service. The terms offered include a gratuity of £1,000 on retirement after six years' service, or £2,500 after 12 years' service, together with free return passages, for those who no longer desire to remain in the Service. In other respects the terms will be as detailed below.

Candidates must be British subjects under 32 years of age at the time of application, and must be registered under the Medical Acts in force in Great Britain and Northern Ireland.

CAREERS

The Indian Medical Service offers wide opportunities of medical experience, including clinical, preventive, specialist and research work. At the beginning of his career an officer is employed on the military side which has medical charge of the Indian Army. Promotion is on a time scale up to the rank of Lieutenant-Colonel and by selection to the ranks of Colonel and Major-General. An officer may apply after one year's Indian service to have his name registered for transfer to the civil side, from which appointments are made to Civil Surgeoncies which are established at the principal civil centres to provide for the medical needs of civil officials and for general medical administrative purposes; to specialist (for example public health and bacteriological) services; to research posts, and to professorships at the Medical Schools.

PAY

The monthly rates of pay for European officers in the Service who have a "non-Asiatic" domicile are as follows:

Rank	Service in Rank	Basic Pay	Overseas Pay	Years of Total Service
1	2	3	4	5
		Rs.	Rs.	
Lieut.	—	500	150	1st
			150	2nd
			150	3rd
Capt.	(i) During first 3 years service as Captain	650	150	4th
			£15	5th
	(ii) With more than 3 and less than 6 yrs. service as Captain	750	£15	6th
			£25	7th
			£25	8th
	(iii) With more than 6 years service as Captain	850	£25	9th
			£25	10th
			£25	11th
			£50	12th
Major	(i) During first 3 years service as Major	950		
	(ii) With more than 3 and less than 6 years service as Major	1100		
	(iii) With more than 6 years service as Major	1250		
Lieut.-Col.	(i) Until completion of 21 years total service	1500	£250	17th and over
	(ii) During 21th and 25th years service	1600		
	(iii) After completion of 25 years total service	1700		
	(iv) When selected for increased pay	1850		

EXTRAS.—In addition to the above rates various allowances are admissible for a large number of special appointments on both the military and the civil side which may be held by members of the Indian Medical Service. Special high rates of pay are also attached to the numerous administrative appointments open to officers in both branches of the Service.

ANTEDATES IN COMMISSION

Any service rendered by an officer during the war as a medical or combatant officer, or in a position usually filled by an officer may be counted as service for increments of pay, promotion, retirement and retired pay, but not for gratuity.

One half of any service in the ranks during the war may be counted as service for retirement and retired pay only.

Candidates possessing certain higher medical qualifications may be granted an antedate of one year in their commissions. Past service in certain hospital appointment may also render candidates eligible for an antedate of one year. Persons holding or about to hold resident posts at recognized hospitals may be seconded in those posts for a period not exceeding one year. The maximum period of antedate secondment or antedate and secondment combined admissible under this paragraph, is limited to one year.

OUTFIT ALLOWANCE

Officers on appointment will receive an outfit allowance of £50.

PRIVATE PRACTICE

With the exception of Administrative Officers, military or civil, and officers holding certain special appointment officers are not debarred from taking private practice, so long as it does not interfere with their proper duties.

LEAVE

Leave can be taken at reasonable intervals, and adequate rates of leave pay are provided. Extra leave (known as study leave) which may not exceed 12 months in all during an officer's service, may be granted to officers desirous of pursuing special courses of study of a post-graduate nature. During such leave, study allowance at present fixed at the rate of 12s. a day in the United Kingdom, £1 a day on the Continent of Europe, and £1 10s. a day in the United States of America is granted to an officer in addition to ordinary rate of leave pay.

PENSIONS

The rates of pension are as follows	Per annum £
After 17 years' service for pension	400
,, 18 ,, ,, ,,	430
,, 19 ,, ,, ,,	460
,, 20 ,, ,, ,,	500
,, 21 ,, ,, ,,	540
,, 22 ,, ,, ,,	580
,, 23 ,, ,, ,,	620
,, 24 ,, ,, ,,	660
,, 25 ,, ,, ,,	700
,, 26 ,, ,, ,,	750
,, 27 ,, ,, ,,	800

These rates are subject to alteration on account of a rise or fall in the cost of living as compared with the year 1919 to an extent not exceeding 20 per cent. in all, the revision being undertaken triennially. With effect from July 1st 1930 a reduction of 5½ per cent. has been made on this account from the amounts shown.

There are additional pensions ranging from £65 to £350 per annum for officers who have held administrative appointments.

PASSAGES

An officer on appointment is provided with free passage to India. The wives and families of officers who are married prior to the date of the officer's embarkation on first appointment will also be provided with free passage to India subject to the payment of messing charges.

Officers and their families are also eligible for passage concessions under which they are granted a certain number of return passages home at Government expense during their service.

INSTRUCTION PRIOR TO EMBARKATION

Officers are required to undergo courses of instruction at the Royal Army Medical College and at Aldershot, lasting approximately six months prior to their embarkation for India on first appointment.

Full details regarding these appointments and forms of application may be obtained from the Under-Secretary of State for India, Military Department, India Office, London, S.W.1. The Selection Committee will meet at the India Office early in January next, and the selected candidates will be required to join a course of instruction commencing early in February, 1931, prior to sailing for India in the Autumn of 1931. Applications should be submitted as soon as possible.

EPSOM COLLEGE

Established in 1855 as a Public School with a Royal Medical Foundation

Patron HIS MOST GRACIOUS MAJESTY THE KING
President THE RIGHT HON THE VISCOUNT BURNHAM, G C M G
Treasurer SIR WILLIAM HALE WHITE K B E, M D
Chairman of the Council RAYMOND CRAWFURD, Esq M D I R C P
Vice Chairman of the Council SIR JOHN F H BROADBENT, Bart, M D
Head Master of the School ARNOLD C POWELL, Esq, M A

EPSOM COLLEGE has an exceptionally fine position with a dry bracing climate on the slope of Epsom Downs The buildings include the War Memorial Chapel large science buildings with lecture theatre and several laboratories for physics chemistry and biology the Holman art room and the Propert library a covered swimming bath heated throughout the year a gymnasium a rifle range a drill hall and armoury a separate sanatorium (60 beds) with X ray department and isolation annexe There are also a museum a carpenter's workshop music rooms fives courts a pavilion and a laundry Large central heating and hot water systems have recently been installed There are over 30 acres of playing fields and 7 acres of vegetables

For boys who have matriculated at the University of London and who desire to enter the Medical Profession the First Medical Examination of that University is conducted at Epsom College and they are spared the expense of going to London for the purpose

The General Council of Medical Education and Registration of the United Kingdom has included Epsom College in the list of Recognized Institutions approved of by that Council as places at which medical study may be commenced and the College has been recognized as a School of Science by the Royal Colleges of Physicians and of Surgeons for the purpose of their Conjoint Diplomas

Boys are also prepared for the Army Navy Air Force Civil Service the Universities and for mercantile careers

Ten Medical Scholarships differing in value and one Dental Scholarship are awarded annually at the Hospital Schools in London and 32 leaving Scholarships ranging in value from £15 to £105 are awarded under varying conditions some of them annually but most of them tenable for several years Besides these there are one Dr Robert Thomson and Phyllis Broughton Open Entrance Scholarship of £120 a year one Domett Stone Open Entrance Scholarship of £50 a year and four Salomons Entrance Scholarships of £50 a year each Hugh Vardon Scholarships of £24 and Junior Open Scholarships of £60 are awarded annually

ANNUAL FEES.—Sons of Medical Men £135 Those who are not the sons of Medical Men £155 Day Scholars £57 These fees cover all the extras which used to be charged for separately under the heading Consolidated Charges'

NEW SANATORIUM

Since the publication of the plans of the New Sanatorium in the Lancet and British Medical Journal in December 1927 the Council with the help of friendly criticism from various Medical friends has reconsidered both the plans and the site A retired but convenient site which stands back a quarter of a mile from the main road away from the noise of traffic has been selected

The revised plans prepared by the Architects Messrs William A Pite Son and Fairweather show a three story building instead of the former two story building The ground and first floors accommodate patients while the second floor is occupied by rooms for the nursing and domestic staff

The main entrance faces North and all wards face South the long axis of the building being East and West

This new plan has made it possible considerably to increase the floor space per bed in the wards and also to add to the number of Bathrooms and Sanitary Annexes The positions of the Minor Surgery Operating Room and the X ray Room have been reversed the former is now placed next to the Casualty Room in the Out patient Wing and the latter near the Entrance Hall

In October last the Council decided that it was imperative to commence building at once and tenders were called for That of Mr E H Smith of Croydon for £26,215 was accepted and work was started on October 16th By the terms of the contract the building is to be completed in June 1931 which will allow time for the conversion of the Old Sanatorium to its new use as a House for 50 boys in September 1931

A sum of over £8 400 has been received towards the cost of the building and the Council will welcome further donations from those who feel that a College so closely connected with the Medical Profession should possess a Sanatorium worthy to be a model for all other Public Schools

A donor of £10 000 may give his own name or the name of any person whom he desires to commemorate to the Main Sanatorium a donor of £5 000 may do likewise to the Isolation Wing while a large ward may be named for £3 000 or a small ward for £1 000 and a single bed for £100

ROYAL MEDICAL FOUNDATION

FIFTY FOUNDATION SCHOLARS receive an education of the highest class in Epsom College and are boarded clothed and maintained at the expense of the College They must be elected after approval by the Council from among the sons of necessitous Medical Men who have been Registered Medical Practitioners for five years

FIFTY ORDINARY PENSIONERS who must be legally qualified Medical Men registered for five years or the Widows of such receive an annual pension They must be not less than 60 years of age at the time of their application for admission as candidates

The Ordinary Pensioners and the Foundation Scholars are elected by the Governors voting by ballot and having votes in proportion to the amount of their contributions There is one election in the year namely in June

The Ordinary Pupils the majority of whom are sons of Medical Men pay fees which cover the entire cost of their board and education

A sum of close upon £9 000 is required annually to maintain fifty Foundation Scholars and fifty Pensioners yet this leaves much destitution in the profession untouched The Council earnestly plead for more and larger subscriptions so that they may extend the work to the relief of this distress

The profession and the public are therefore asked to make the Royal Medical Foundation attached to the College a refuge in time of trouble for all those members of a great profession and their children who fall on evil days

Donors of 10 guineas and collectors of 20 guineas are Life Governors of the College subscribers of one guinea annually are Governors during the continuance of their subscriptions

Peptalac REGD

THE NEW INSTANT PREDIGESTED FOOD

Predigestion of starch *and* milk is guaranteed and is effected under the most exact scientific conditions in our laboratories before powdering This means that when required for use it can be immediately and simply prepared by the *mere* addition of hot water The C & G Improved Roller Process is used ensuring retention of the full mineral and vitamin content with freedom from pathogenic organisms

PEPTALAC is indicated in all those cases where the powers of the digestive tract are insufficient to deal with that amount of food necessary for maintaining health—for nursing mothers with weak digestions, in ante- and post-operative surgical cases, in achlorhydria, peptic ulceration, cancer of the alimentary tract, in all forms of convalescence and in old age.

THE CONSTIPATION SYNDROME

Whether the symptoms associated with constipation are partly toxaemic or entirely due to neuro-muscular disorder, there is no doubt about their reality or their gravely disturbing effect on bodily and mental efficiency

The influence of emotion, acting through the mediation of the sympathetic nervous system, on bodily processes—markedly on those concerned with alimentation and elimination—is reversible, the psychic consequences of discordant activity of the involuntary muscles being no less striking

Many vague discomforts and disturbances of health which are often brushed aside as neuroses, or as consequent on undefined focal infections, are, in fact, brought about by disharmonized or ineffective peristalsis

Thus, we suggest, is explained the undoubted benefit which patients suffering from such disturbances often derive from a morning glass of Eno's "Fruit Salt," taken regularly over a period of a few weeks In addition to—or by reason of—its purity and its complete freedom from such mineral salts as Epsom and Glauber, Eno is pleasant and refreshing to the palate, as well as effective in action It has the further merit of being non-habit-forming

"Urgent Abdominal Diagnostics"

The Proprietors of ENO'S Fruit Salt will deem it a privilege to send to any member of the Medical Profession a copy of the latest of their series of 'Medical Reminders'—with or without a bottle of their preparation as desired Urgent Abdominal Diagnostics summarises the salient facts which need to be ever at the front of the mind when faced with an abdominal emergency The diseased conditions dealt with include those which most often call for immediate surgical attention It is bound in black morocco limp to conform to the style of the previous publications in this series
